The Second Economy and the Destabilizing Effect
of its Growth on the State Economy
in the Soviet Union: 1965-1989

INTRODUCTION[1]

This study is focused on the second economy[2] in the Soviet household sector and its links to the official state economy.

The paper examines the relationships between per capita legal money income and such income-dependent variables as per capita savings, and purchases of various goods and services in state trade in a large number of regions in Russia and Ukraine in the period between 1965 and 1989. The relationships display, not unexpectedly, a high degree of correspondence between income and most dependent variables in the 1965-1970 period.[3] In this regard the Soviet household sector's income-expenditures behavior was similar to that of other economies, centrally-planned and market. The interesting phenomenon is that after the starting years of our study, 1965 for Russia and 1970 for Ukraine, and virtually without exception the close degree of correlation measured by simple cross-sectional regression analysis begins to get weaker and weaker and almost disappears by the end of 1980s. We speculate that the most likely explanation of this phenomenon is the emergence and rapid growth of the second economy. We view the process as follows.   Legal state income and transfers to households would be increasingly supplemented by illegal second economy earnings. At the same time patterns of purchases of goods and services through state channels would be increasingly distorted by expanding alternatives available in private or black markets. And, it should be noted, opportunities for earning second economy income and the need to move to alternative markets would vary among households. Thus, some

---

[1] An earlier version of this paper was read at the annual convention of the American Association for Advancement of Slavic Studies, Honolulu, November 1993. The authors wish to thank Dr. Misha Belkindas for his comments and suggestions.

[2] We use the definition of the second economy in the USSR proposed by Professor Grossman. According to this definition, "the second economy comprises all production and exchange activity that fulfills at least <u>one</u> of the two following tests: (a) being directly for private gain; (b) being in some significant respect in knowing contravention of existing law." (Grossman, 1977, p. 25.) The classic papers on the topic of the Soviet second economy are Grossman (1977, 1979).

[3] The evidence derived from a different set of data stronly suggests that the high degree of correspondence between income and expenditures on basic foods had existed in Russia as far back as 1957 (See Appendix C).

households would enjoy higher incomes without having to pay second economy markups on goods they buy while some would suffer from a decline in their real income caused by higher black market prices without having additional second economy income. The rapid spread of the second economy, therefore, would explain how the orderly and "balanced" relations between income and material flows became gradually disjointed and "unbalanced" as long as planners and economic administrators neglected to take second economy activities into account.[4] We could also speculate that if this was true the emergence and rapid growth of the second economy since mid-1960s contributed to the deepening economic crisis of the late 1980s and the ultimate disintegration of the Soviet economy.

The study is exclusively based on official Soviet statistics covering only legal or state disorder money flows, particularly on data on legal money incomes broken down by regions which became available recently and our conclusions with respect to the second economy phenomenon are drawn indirectly. The method employed by us can be thus likened to the method used by an astronomer who seeks to discover the existence and trajectories of unseen heavenly bodies by studying perturbations and peculiar behavior of visible ones.

The second economy phenomenon in the Soviet Union has been studied extensively in the West in the last 20 years or so and much was learned about its specific markets, institutions, products, and mechanisms as well as about the overall magnitude of private incomes and employment (Grossman, 1990). There is no doubt that by the late 1970s, the Soviet second economy had grown to be fairly large relative to the first or the official economy. Professor Grossman has estimated that in the late 1970s, private income comprised between 28 and 33 percent of total household income (Grossman, 1987). One of the authors of this study complemented Grossman's income figures by estimating that the second economy employed between 10 and 12 percent of the total labor force (Treml, 1992). These

---

[4] "Annual money income and expenditure balances of the population" from which our income data were taken has been one of the key Soviet documents in planning and administering the household sector. These statistics have been used by Gosbank in preparation of cash flow plans, by Gosplan and Ministries of Finance and Domestic Trade in planning retail trade turnover and deliveries, and by other agencies controlling incomes and expenditures of the population. Until the early 1990s both the planning and ex post "balances" were classified (Boyarskii et al., 1986, pp. 20-21; Garbuzov et al., eds, 1984, pp. 69-70; Nazarov, ed. 1982, p. 518-519).

and similar estimates, however, must be taken as first approximations because they depend to a large extent on specific assumptions and statistical weights employed in normalization. The veil of secrecy surrounding second economy activities (most of which being illegal) is an important but not the only explanation of the difficulty of arriving at accurate figures. An equally important factor is that so far there has been no consensus as to statistical conventions, classifications, and accounting rules applicable to second economy phenomena.

Unfortunately, Western studies (and the available Soviet studies discussed below) have failed so far to arrive at any conclusions on two rather important and interrelated aspects of the second economy: the first is the dynamics of second economy over the last 20-25 years, and the second is the impact of the second economy on the overall performance and allocative efficiency of the "first," i.e., the state economy. The greatest difficulty with tracing the dynamics of the second economy has been the lack of reliable and consistent time series aggregate data.

The three major surveys of emigrants from the USSR conducted in recent years cover different time periods, are not directly comparable, and have a number of possible biases.[5] From these surveys we have learned a great deal about household budgets, regional differences, consumer behavior, housing conditions, employment environment and the like. Unfortunately, these surveys yielded little useful data related to intertemporal changes in private incomes and expenditures. Moreover, only the Berkeley-Duke survey focused explicitly on second economy activities.[6]

The second economy may be large relative to the official state economy but without having some idea of rates of growth of the two it would be difficult to discuss the interaction

---

[5] For the survey conducted in Israel see Ofer and Vinokur (1991). Millar (1987) offers a detailed summary of results of the so-called SIP survey.

[6] The Berkeley-Duke household budget survey covered 1061 households with 2963 individuals who emigrated from different urban regions of the USSR, the largest city subsamples being from Erevan (191 households) and Leningrad (303 households). Central Asian republics were not covered except from a small group of households from Uzbekistan. Households reported on their incomes and expenditures during their "last normal year" in the Soviet Union. The overwhelming majority of responses pertained to the period between 1976 and 1981. The survey paid particular attention to the second economy activities of Soviet households both as producers and consumers. Most studies based on the emigre survey and other sources have been published in BERKELEY-DUKE OCCASIONAL PAPERS ON THE SECOND ECONOMY IN THE USSR series of which 36 issues have appeared so far. Professors Alexeev, Grossman, and Treml served as the principal investigators of the project.

between them and the consequences of this interaction. Suppose, for the sake of argument, that the second economy has always been a relatively large and a constant component of the overall Soviet economy or that its share varied within a narrow range. Then we would have to conclude that over time the two economies have developed a certain modus vivendi allowing them to coexist without overt conflict or even to support and complement each other. If, on the other hand, the shares of the two economies in the total have been changing over time we would infer some alteration in relations which could be of antagonistic or benign nature.

The growth of the second economy is not the only factor affecting the relationships between household incomes and such dependant variables as savings and purchases of different goods and services. During the period examined in this study, i.e., 1965 to 1989, a large number of micro and macro economic, demographic, social, and regulatory changes have taken place in the Soviet Union all or some of which could have influenced these relationships.

Let us consider savings. The two basic forms of savings accounts in the Soviet Union were named accounts and bearer accounts ("schet na predstavitelya") and the latter, because of its anonymity, have always been favored by second economy entrepreneurs. Gosbank essentially obliterated the anonymity in 1978 by instructing savings banks to allow fund withdrawal only upon presentation of passports (Gosbank, 1981, p. 79). A study of savings in one oblast showed that both the number and the average size of bearer accounts' deposits were drastically cut following the change of regulations (Anurin, 1988, p. 54). We could have thus expected that the relationship between household legal incomes and bank savings would have undergone some changes around 1978; in fact, one could argue that a partial removal of funds earned in the second economy from savings accounts would have strengthened the correlation between income and savings as measured in our study.

We could cite many other examples of developments which could have and probably did affect income and expenditures relationships in the 1965-1989 period in the positive or negative direction. In some cases, of course, the effects of these changes could have cancel each other. The continuing deterioration of the strength of these relationships as measured by

R^2 clearly suggests the presence of a single major factor which dominated the developments in this period, and which we identify as the growth of the second economy.

Some caveats are in order at this point. This study focuses exclusively on income and expenditures within the household sector. The second economy, needless to say, permeates the state sector and affects and distorts relations among state producers, but these effects are outside the scope of this study.

Since we are using cross-sectional data it is important to note at this point that all Western studies and anecdotal evidence from Soviet sources strongly suggest distinctly different regional patterns of second economy activities and transactions. Both in terms of ruble value and frequency of occurrences of transaction and in terms of labor inputs the second economy was more conspicuous in the South (Armenia, Georgia, Azerbaidzhan, and Central Asia), less so in the West and the North (Russia, Ukraine, Byelorussia, and Moldavia), and marginally lower in the Baltics (see for example Grossman, 1979 and 1987). The present study, on the other hand, is focused exclusively on Russia and the Ukraine, i.e., regions with a relatively lower level of per capita second economy activities. It would thus be reasonable to argue that were the necessary statistical data available for the South and other regions of the USSR the findings would be even more striking.

The study is organized as follows. The next section examines the relatively recent recognition of the existence of the second economy by Soviet authorities and their reaction (or, actually, non-reaction) to it. Section 3 analyzes the available official statistics and discusses the method used by us of linking these statistics to the analysis of the dynamics of the second economy. Section 4 addresses the implications of the growth of the second economy for the efficiency of the Soviet economy. Detailed statistical data, notes, and documentation are covered in three appendixes. A bibliography of Western and Soviet sources completes the study.

RECOGNITION OF EXISTENCE OF THE SECOND
ECONOMY BY SOVIET AUTHORITIES

Soviet economists and statistical and planning agencies and research institutes were late in recognizing that the second economy was a unique component of the national economy and not just a mere aggregate of economic crimes. Some individual economists have been researching various second economy phenomena since the mid 1970s, but published studies lack documentation and the necessary definitional, classificational and methodological notes.[7]

Tatiana Koriagina, one of the more visible Soviet specialist in issues related to the "shadow economy," published a number of papers and articles in newspapers and academic journals starting in the early 1980s. But as with other Soviet writings her contributions are poorly documented and often contradictory and are closer to "economic journalism" than scholarly research. In several of her papers Koriagina reported her estimates of the overall magnitude of the second economy which grew from approximately 5 billion rubles in the early 1960s to 90 billion rubles in the late 1980s. However, she concedes the approximate nature of her estimates, reporting that the figures for the early 1990 ranged from a low of 20-25 to a high of 150 billion rubles; the increase from the early 1960s thus ranged from four-fold to 30-fold.[8] Koriagina's estimates of the number of people engaged in the second economy was something less than 8 million in the early 1960s to about 30 million in 1989. The much slower three-fold growth of the labor input compared to the growth in rubles is puzzling unless we are willing to accept the notion of an extremely rapid increase in the rate of remuneration.

---

[7]Valeriy Rutgaizer, one of the earlier Soviet economists to recognize the importance of the second economy and to initiate research, published a useful summary of Soviet studies in English (Rutgaizer, 1992).

[8] In order to suggest some order of magnitude we may note that Soviet national income (Net Material Product) in current prices increased from 145 billion rubles in 1960 to 701 billion rubles in 1990. Estimates of second economy income made by Koriagina or others cannot be directly compared to official national income. There is large number of complex accounting issues which we cannot cover here. For example, a large share of second economy income is generated in the service sector but services are not counted in Soviet national income accounts.

Official Soviet statistical agencies did not offer more coherent figures and, in fact, only added to the general confusion. The first recognition of the existence of the second economy in the USSR appeared in a 1989 Goskomstat statistical compendium. According to this sources the "unearned income of the population" (which was apparently equated with the second economy) grew from 3 billion rubles in 1975 to 5.1 billion in 1986 (Goskomstat SSSR, SOTSIAL'NOYE... 1989, p. 99). One year later a similar compendium reported "selected categories of illegal income" for 1989 as 56.5 billion rubles but it was not clear whether second economy incomes increased so rapidly between 1986 and 1989, or whether definitions and the coverage of private activities and transactions had changed between the first and the second report (Goskomstat SSSR, SOTSIAL'NOYE ... 1990, p. 121). The upward revision of second economy estimates continued unabated -- the next year compendium revised the 1989 estimate from 56.5 to 59 billion rubles and reported the 1990 figure as 68.8 billion rubles (Goskomstat SSSR, SOTSIAL'NOYE RAZVITIYE... 1991, p. 127). The latter figure was almost immediately revised upward to 99.8 billion (Goskomstat SSSR, PRESS-VYPUSK, 1991, p. 1). Official Goskomstat SSSR sources while giving more detailed breakdowns of total "illegal incomes" have not, however, offered definitions of various categories or explanations of how the estimates were made.[9]

It can thus be concluded that Soviet sources while offering a rich diet of anecdotal material and some interesting but often ambiguous quantitative references cannot be used to close the gap in our understanding of the record of growth of second economy in the USSR.

Soviet sources on the second economy were equally sparse in the analysis of the interaction between the second and the first economies and the overall impact of the former.[10]

---

[9] Professor Treml interviewed a number of Goskomstat SSSR officials concerning second economy estimates and was given some internal experimental methodological documents. One reason for the confusion with estimates published in Goskomstat compendia lies with the sources of statistics -- Goskomstat made only a few estimates of specific illegal activities relying on a group of academic institutes and law enforcement and financial agencies for the rest. In each case definitions and methodology of estimation seemed to have been different.

[10] Some economists (e.g. Tatiana Koriagina mentioned above) roughly estimated tax losses produced by the concealment of productive activities but did not go beyond these estimates.

The consensus among Soviet scholars was that the second economy (under which they almost invariably understood both illegal private economic endeavors and purely criminal activities) had an adverse impact on the official state economy because of its corrupting influences, generation of "unearned" and "illegal" incomes and by creating conditions conducive to emergence of organized crime. And, while they clearly perceived the causal relationship between shortages of state-produced consumer goods, state-fixed low prices, and the resulting activities of "speculators," they did not suggest (at least not openly) that without the "speculators" the state distribution system would have operated at an even lower level of efficiency. It can also be said that most Soviet commentators and policy makers going back to Lenin in the 1920s traditionally attributed more sinister significance to black markets than warranted by the historical record or theory. The "speculators," according to the prevalent view, were not mere middlemen benefitting from arbitrage made possible by excess demand but active agents creating artificial shortages by cornering markets, destroying or hoarding goods, and by other monopolistic strategies. Needless to say, this view of black markets was self-serving as it transferred the blame for consumer goods' shortages from state bureaucrats to private entrepreneurs.

A comprehensive analysis of Soviet official attitudes towards private economic activities is beyond the scope of this paper. Even the most perceptive economists of the Gorbachev era such as Shatalin, Petrakov, Yasin, and Men'shikov, to name just a few, in their analysis of the deepening economic crisis of the late 1980s referred vaguely to growing "imbalances" which plagued the system without explicitly identifying economic forces producing these imbalances.[11]

The most analytically positive was Shatalin's "Five-Hundred Days" program which emphasized the size and the importance of the second economy. The Program stated that "the

---

[11] In a tantalizing but undocumented paragraph, Stanislav Men'shikov refers to an econometric model of the Soviet economy he constructed in the early 1970s in Novosibirsk. The model "... helped to identify the presence of <u>black holes</u> in, among other areas, balances of money income and expenditures of the population ... which could be explained by the existence of a large illegal shadow economy." According to the author, the work on the model was disapproved by the then director of the institute, Abel Aganbegyan. But the author contradicts himself. Later in the book Men'shikov notes that "during Brezhnev's years the growth of underground business proceeded gradually and without surfacing too much" and its growth accelerated only during the years of *perestroika*. (Men'shikov, 1990, pp. 4-5, p. 191).

logic of transition to markets presupposes the utilization of 'shadow' capital in the interest of all people" and described the second economy as an important factor in the resource support of reforms. The authors of the program expected that as much as 90 percent of second economy activities would be absorbed by emerging free markets (Shatalin et al., 1990, pp 124-127).

The complete failure to understand the nature and origins of the second economy and to formulate appropriate policy recommendations could be illustrated by May, 1991, deliberations at the Secretariat of the Central Committee, CPSU, focused on the "shadow economy." Alarming reports on the spread of economic crime were delivered by the head of KGB, Vladimir Kryuchkov, the head of MVD, Boris Pugo, and the Prosecutor General of the USSR, Nikolay Trubin. All second economy phenomena were lumped together as criminal ("economic banditry and mafias") resulting from "violations of economic links, the ruin of consumers markets, attempts of local authorities to administer the markets by noneconomic methods, breaches of deliveries and distribution of consumer goods, and creation of artificial deficits." It is clear from the tone of deliberations that most speakers blamed the rapid spread of the second economy on "perestroika." Policy recommendations discussed at the session was the familiar party drivel -- greater involvement of the Party cadres in the struggle against economic crimes, cooperation with local authorities, and a more forceful promotion of the "party line" with law enforcement agencies were called for ("Protiv...", 1991, p. 2).

In summary we will thus note that for a long time Soviet authorities did not identify or study the second economy; after the presence of large-scale second economy activities was recognized it was viewed as consisting of separate and unrelated phenomena to be controlled by law enforcement agencies and state regulations and not requiring reforms or changes in existing state institutions and economic policies.

LINKING THE FIRST AND THE SECOND ECONOMIES
THROUGH OFFICIAL STATISTICS

Certain relationships among economic variables presumably exist in an economic system, whatever its type. For example, savings and consumption should be highly correlated with consumer income in the Soviet as in any other economy, all the more so, since consumer behavior was not explicitly planned even in the USSR.

Of course, in order to establish these relationships one has to measure the relevant variables appropriately. For instance, savings in the state owned savings institutions did not represent the entire monetary savings of the Soviet consumers. At least part of these savings were held in the form of cash, "under mattresses" or, as they say in Russia, "in a *kubyshka*."[12] Similarly, officially recorded income and officially recorded consumption of various goods and services did not adequately reflect the corresponding actual values. Presumably, the less accurately income and other variables are measured, the weaker is the observed relationship between income and these variables.

Using simple linear regressions on cross-sectional data from Russian and Ukrainian regions we evaluated the degree of linear dependency between income and savings, income and retail trade turnover, and income and sales of various goods in state trade. We discovered that R^2 of these regressions has been declining over time (see Table 1 and Diagrams 1-7). In other words, cross-sectional regressions for later years generally had significantly lower R^2 than the corresponding regressions for earlier years. We will argue that this decline reflects the growth of the second economy in the USSR.

---

[12]We can assume, however, that most Soviet households had a preference for keeping their liquid funds in savings banks rather than in the form of cash; only household with large illegal incomes derived from second economy or criminal activities would be afraid of possible exposure through savings accounts. In the 1947 monetary reform in which currency of a new design replaced existing ruble bills cash was exchanged at the rate of one new ruble for 10 old rubles while savings were exchanged at a much more favorable rate. During the 1961 monetary reform all funds were exchanged at a 1:1 rate but people were clearly afraid to exchange what they considered to be excessive amounts of cash.

The idea of our approach can be illustrated by the following stylized example. Suppose that the true savings function of the consumers in a given region in year 0 is represented by[13]

$$s_i = a + by_i \qquad\qquad (1)$$

where s_i is the amount saved by region i consumers out of their current income y_i, and a and b are fixed coefficients. If both income and savings are measured correctly, a linear cross-sectional regression of savings on income would produce R^2 equal to 1. Suppose now that in year 1 each region experienced an officially unrecorded increase in income due to second economy activities, $\Delta y_i \geq 0$. If savings function (1) does not depend on the source of income, the increase in savings is $\Delta s_i = b\Delta y_i$ and the new savings are equal to

$$s_i + \Delta s_i = a + b(y_i + \Delta y_i) \qquad\qquad (2)$$

Assuming that the resulting change in savings has been officially recorded, the regression of recorded savings on recorded income would produce different regression coefficients a' and b', and, in general, would have $R^2 < 1$. It is possible to show that the decline of R^2 in this situation would measure the growth of the second economy only to the extent to which Δs_i cannot be expressed as a linear function of y_i. Similarly, if we use more than one independent variable then the changes in R^2 would reflect the dynamics of the second economy only as long as the observed changes in the dependent variable are not described by a linear function of both independent variables. Clearly, introduction of an additional independent variable would reduce the informational content of R^2 for our purposes. In this case the researcher has to be willing to interpret the estimates of the regression coefficients -- a highly unreliable technique with these particular data.

---

[13] Note that, due to limited data availability, we used the stock of savings, not their annual flows in our regressions. Nonetheless, in the following illustration we use incremental savings. This is done because in almost all other regressions we used flow variables.

Similar arguments can be used for the case when the initial R^2 is not unity.[14] The reasoning would be essentially the same if both income and savings changes were only partly reflected in the official statistics.

On a more substantive level, suppose that consumer incomes are growing but the state supply system constrained by the rigidity of official prices is not able to satisfy growing aggregate demand for consumer goods. Without the second economy, growing incomes accompanied by only slowly growing supplies of consumer goods would disturb the original relationship between income and savings, as well as between income and consumption. This would happen mainly due to the accumulation of excessive savings by the population.

These "forced savings," however, would not represent a long term equilibrium mainly because they provide strong incentives for second economy activities.[15] The emergence and growth of the second economy would redistribute incomes among groups of population and among regions, most likely exacerbating the observed imbalance in the official markets. In addition to the aggregate shortage, the insufficient responsiveness of the state supply system to the changing structure of consumer demand would produce further incentives for the development of the second economy.

With respect to the state-run retail trade network we can expect the following:

■　　Households which experience relatively large income growth from whatever source will increase their demand for (normal) goods and services offered in state retail trade.

■　　The increased demand generated by growing private incomes will be satisfied by additional deliveries to the trade network if the state supply system is flexible and responsive to demand pressures. If the supply system is not sufficiently flexible, and since state fixed prices do not respond to demand changes, shortages will result. The unsatisfied households would have to seek the goods in question in the black market or "from the back door" of state stores.

---

[14] Strictly speaking, in this case additional assumptions would be necessary about sufficiently small correlation between errors in the initial regression, initial incomes, and increments to savings.

[15] For a discussion of the applicability of the concept of "forced savings" to the USSR see Alexeev (1988).

■ Shares of certain goods produced by the state and distributed through the state retail trade network are in reality not consumer goods (i.e., goods the demand for which is determined by consumers' income) but intermediate producers' goods. For example, large quantities of bread and bakery products are used illegally as livestock feed, sugar is used in illegal home production of alcohol, building materials are used by semi-legal *shabashniki*, i.e., informal construction teams.[16] Demand for these goods which are classified as consumer goods by planners is in fact determined not by purchasers' income but by the demand for goods produced (illegally most of the time) by purchasers.

■ In addition to goods and services originating from the state system, the growing second economy will be offering illegal or unavailable goods and services (appliance repair, spare parts, smuggled foreign goods, services of prostitutes, drugs, prohibited books and records, etc) affecting the expenditure pattern of some households and thus changing their purchases in state stores.

■ In many instances, the turnover and the mix of goods in state stores will be also affected by surreptitious injection of goods undistinguishable from state-produced goods but in fact manufactured in clandestine second economy enterprises.

■ The appearance and growth of the second economy would have varying effects in different localities, towns, and regions. Some may enjoy substantial increases in total (state and private) incomes while income growth in others may be modest. Accordingly, the imbalances in the regional state-run markets would differ in degree. In each region, however, the orderly relationships between average money income of the population (i.e., legitimate state income) and purchases of many goods and services in state retail trade extant in a period marked by the absence or minimal presence of

---

[16] The quantities involved are quite large. For example, bread used as livestock feed in subsidiary private agriculture was estimated at between 10 and 13 percent of total bread sold in retail trade (SOTSIAL'NOYE RAZVITIYE... 1989, p. 99); approximately 18 percent of sugar sold in retail trade in 1990 was diverted from human consumption for the estimated production of 1.5 billion liters of 40 percent moonshine (Goskomstat USSR, Press-vypusk..., 1991, p. 2). The data on retail trade sales are from Goskomstat SSSR, NARODNOYE..., 1991, p. 131.

the second economy, should be significantly disturbed by the growth of the second economy.

At this point we would like to make several additional remarks about the effects of the second economy on consumption and savings patterns of the population. First, with a few exceptions, money prices in the second economy were significantly higher than in the first economy. The large differences in the posted money prices, however, masked the fact that the effective prices of goods and services in the two economies were in fact quite close.[17] Consumers had to queue up or search for goods in the first economy adding time costs to their effective prices. Also, the first and second economy goods were often difficult to compare in terms of quality[18] and with respect to the amount of customer fraud that took place during sales. For these reasons, it is difficult to ascertain the precise income and substitution effects on overall consumption pattern produced by purchases in the second economy.

Second, the effect of black markets on consumer behavior may, in general, depend on the society's perception of the morality of black market activities. Berkeley-Duke emigre interviews and evidence in the Soviet media suggest that Soviet people are not much different from people in other societies and cultures. Thus, a certain share of the population considers active participation in some "strongly" unlawful second economy activities such as production of illegal goods and services, theft from places of employment, shortchanging or cheating customers or clients, exacting bribes or favors, and large scale "speculation" to be "immoral and reprehensible." A much larger share of the people, however, accepts without misgivings other types of participation in the second economy, such as moonlighting, purchasing black market goods, paying bribes and extending favors to officials, offering premiums and illegal gratuities to service personnel above state-fixed rates, and the like. It would thus be reasonable to expect that the impact of the growth of the second economy would be based

---

[17]If it is possible to resell goods purchased in the first economy in the black market at zero transaction costs, the effective prices in the two economies would be the same. See Stahl and Alexeev (1985).

[18]Sometimes the second economy goods were generally considered to be superior on average, e.g. meat at kolkhoz markets. In other cases, such as with some types of hard liquor, the first economy products were had higher quality.

mostly on purely economic factors, and would not be confined to any particular group of the population.

Third, the Soviet second economy often has been described as mostly a redistributive activity. From this point of view, the second economy should not affect the aggregate values of savings and consumption in the system, except to the extent that preferences of the second economy operators are different from preferences of their customers. Even purely trading activities, however, may have very significant effects on aggregate savings and consumption. Consider, for example, a household which receives an extra 100 rubles of official income and has a marginal propensity to save of 0.2. If this household does all its shopping in the first economy, this income would add 20 rubles to aggregate savings and 80 rubles to aggregate consumption. But what if the household divides its consumption between the first and the second economy equally? Then it would save 20 rubles and provide an extra 40 rubles of income to the second economy operator, who will in turn save 8 rubles (if her saving propensity is also 0.2 and her cost of goods sold is zero). The total amount of savings is now 28 rubles.[19] Moreover, the presence of the second economy changes both the transaction and the precautionary demand for money by altering the consumers' opportunities to earn and spend money.

Finally, there is one important difference between the savings-income and retail trade-income relationships. Notice that we used regional data in our analysis. It is possible, even likely, that centrally planned allocations of consumer goods to regions depended to some extent on official consumer income in these regions. For this reason, we expect the relationship between official savings and official income to be more affected by the second economy than the retail trade-income relationship.

---

[19]Of course, if the second economy operator worked for the state instead, she would have earned some money also and saved 20% of that. To argue this case, however, we would have to make some rather restrictive assumptions, for example, about availability of employment opportunities in the absence of the second economy.

Let us now return to the data presented in Table 1. Are there other explanations for the decline of R^2 in our regressions besides the growth of the second economy?[20] We consider one such possibility below. While it is not likely to account for such a strong trend in R^2, we note that it and our previous explanation are not mutually exclusive.

The relationships estimated in our regressions may become less linear at different real income levels. In this case, the strength of the linear relationships might have declined due to either growing or decreasing real incomes of the regions. In other words, if real income in 1965 was very low, and if the strength of (per capita) savings-income relationship is inversely related to real income, then growth of real income between 1965 and 1970 would result in lower R^2 in 1970 regressions. A related reason is that income distribution among the regions might have changed over time altering the relationships among the official data. For example, if regional income inequality had been decreasing then it might be more appropriate to compare the full sample regressions for the later years with the earlier year regressions for the middle range of the sample (i.e., without the outliers).

Consider first the influence of changes in interregional income distribution. The distribution of income and of other official characteristics among Soviet regions did change significantly between 1965 and 1989. The Gini coefficients for distribution of average income of regions declined from 0.157 in 1965 to 0.099 in 1985 and to 0.098 in 1989. The coefficients of variation of average regional income decreased from 0.397 to 0.259 and 0.254, respectively. The lower regional dispersion of income, other things being equal, could have caused weakening in the relationship between income and various characteristics of consumer behavior.[21] Changes in income distribution, however, do not appear to explain everything.

---

[20]Strictly speaking, the relationships among official data could be affected by shifts in the geographical distribution of the second economy, instead of its overall growth. For example, if the second economy activities used to be uniformly distributed among the regions but later somehow became unevenly distributed, we would also observe declines in official data correlations. Such a situation appears to be very unlikely, however, as it is difficult to think of the reasons for significant locational shifts in the second economy.

[21] In the limit, if all regions had the same average per capita official income then R^2 would have been zero for any non-constant dependent variable. More importantly, imagine that for one sample the data on income and savings form an almost perfect circle so that the slope coefficient is arbitrary and R^2 is close to zero. Then an introduction of one outlier would immediately "fix" the slope coefficient and significantly increase R^2. For this reason, in order to achieve comparability it might be necessary to remove outliers from some of the annual samples.

For example, consider the relationship between income and savings. First of all, notice that the decline in income inequality was accompanied by an even more precipitous decline in inequality of interregional savings distribution. The coefficient of variation of per capita official savings went from 0.496 in 1965 to 0.219 in 1989. Second, if we eliminate income outliers for the earlier years (1965, 1970, 1980) so that the remaining sample has about the same degree of income inequality as the full sample does in 1985 and 1989, the trend toward lower R^2 remains, albeit in a somewhat weaker form.

The changes in the average level of real income in Russia and Ukraine also do not explain the trends in R^2 for regressions of either savings or retail trade turnover on income. Presumably, real income of Russians and Ukrainians grew at least between 1965 and 1970 and, possibly, even later. Within moderate income ranges the relationship between savings and income is usually stronger at higher income levels. In fact, in our Russian data, R^2 for the richest half of the regions in all annual income-savings samples is much higher than R^2 for the poorest half of the regions. Nonetheless, we observe a precipitous drop in R^2 between 1965 and 1970, as well as for later years. Similar arguments can be used with respect to the relationship between retail trade turnover and income.

IMPLICATIONS OF SECOND-ECONOMY GROWTH FOR SYSTEM EFFICIENCY

Our analysis suggests that the second economy was growing rapidly between 1965 and 1985. Meanwhile, the performance of the Soviet economy in general seems to have been deteriorating over the same period of time. Did second-economy growth exacerbate or alleviate the economic downturn? The implications of the existence of the second economy for efficiency of the Soviet-type economy have been rather extensively studied in the literature. We will offer a brief non-exhaustive survey and some additional comments.[22]

---

[22]In the present paper we have concentrated on the second economy in consumer markets. The so-called shadow economy in the area of intermediate goods production has been large and, presumably, growing as well (see Grossman, 1982). In this section we will comment on the efficiency implications of the second economy in both producer and consumer goods markets.

Clearly, second economy transactions among socialist enterprises, usually being voluntary, benefit the transacting enterprises (managers). The question about whether second economy activities benefit the society at large can be considered in two steps. First, did it facilitate plan fulfillment, and second, did plan fulfillment benefit the society. While the second question might be more important, it was the more specific first question that has attracted a greater amount of attention in the literature. Montias and Rose-Ackerman (1981) have argued that a mutually beneficial transaction between two enterprises may easily be detrimental to the rest of the economy if other enterprises are somehow prevented from bidding. Their argument assumed that the initial planned allocation of inputs was at least close to efficient in a sense of equating marginal rates of technical substitution among user enterprises. They noted that inefficiency of the plan allocations would make second economy transactions potentially more efficient. Of course, if some firms are handicapped in bidding for inputs free market allocations need not be efficient either. The impediments to wide participation in bidding on particular deliveries, however, are presumably much greater in the second economy than in the western-type market economy. By their very nature second economy negotiations are not widely advertised. In fact, difficulties in disseminating information constitute one of the most significant problems for functioning of the second economy.

Ericson (1981, 1983) argued that second economy reallocation of inputs in the absence of informational problems represents Pareto improvement over the planned allocation.[23] Ericson's models, however, assume that managers' utility functions depend only on official output of the enterprise and its final holdings of official funds in the state bank. Of course, the Soviet managers were interested in plan fulfillment but Ericson's assumption disregards any tradeoffs between plan fulfillment and unofficial personal enrichment. Such tradeoffs were surely present given the size of the second economy in consumer markets. Introducing cash holdings (illegally obtained income) into managers' utility functions would destroy the Pareto improving nature of the second economy reallocations of inputs. A manager may sell

---

[23]In Ericson's model second economy transactions are facilitated by cash side-payments. This cash can leak out of the system to induce economic agents to participate in illegal transactions. Because of this leakage the outcome may not be (constrained) Pareto optimal in a sense that some efficient trades may not be performed prior to disappearance of all cash due to this leakage.

part of the enterprise's input allocations or its output in order to obtain extra cash even if this sale hurts the enterprise's plan fulfillment. The more important the weight of cash holdings in the utility function of a manager, the likelier the negative effect of the second economy on official performance. The growth of the second economy in consumer markets probably has been increasing the attractiveness of (unofficially accumulated) cash.

In addition to reallocating inputs, the second economy may attract part of the work force into completely unplanned production of consumer goods. While this in itself may be beneficial to consumers, the planners' actions in response to this redistribution of the economy's resources may reduce the efficiency of the entire economy.[24]

The issue usually discussed in evaluating the role of the second economy in intermediate inputs market is whether or not it facilitated plan fulfillment. This, however, appears to be a rather unreliable criterion of overall efficiency implications of the second economy. A serious problem with the second economy's role in a Soviet-type system is that it may facilitate achievement of "wrong" goals more or less arbitrarily imposed by the central planners. If the second economy facilitates fulfillment of such a plan it may actually deduct from the efficiency of resource use in the economy. In the Soviet Union in particular the planners usually gave priority to heavy industry at the expense of consumer goods production. Helping fulfill such a plan may not be a good thing. A related problem arises when the second economy weakens or even destroys the feedback to the planners from their actions, covering up the shortcomings of the planned allocations and preventing the planners from realizing their mistakes. For example, suppose that skis were shipped to the southern port of Odessa but there was a shortage of skis in the north of the USSR. The second economy operators would rectify the mistake and deliver the skis to the north (at the cost of additional transportation), but the planners would not learn about the mistake and might keep allocating the skis to Odessa in the following years.

In this respect, the Soviet planners may be likened to a driver of a car who sees a very distorted image of the road. When the road conditions change, the driver tries to adjust. The

---

[24]See Wellisz and Findlay (1986). Note, however, that the planners there are rather unsophisticated in that they do not understand the full extent of their actions' consequences which were displayed in Wellisz and Findlay's model.

problem arises when the driver sees a pothole on the right side of the road, while in reality it is on the left side. The driver's maneuver to avoid the false image may lead right into the actual pothole.

Significant inefficiency of second economy operations results from transactions costs being quite high there due to costs of obtaining reliable market information, difficulty of enforcing contracts, and the possibility of punishment.[25] Also, second economy production may suffer from its small scale.

Inefficiencies of another sort arise in situations where the second economy is introduced into consumer markets to reallocate the first economy's allocation achieved through queuing (or search). Allocation of goods through queuing alone is obviously inefficient mainly due to the expense of time on waiting. Also, because marginal value of time would not in general be the same among individuals there would be room for improvement by allowing people to trade goods acquired as a result of queuing (or in effect letting some people hire others to queue instead of them). Allowing for resale of goods purchased in the first economy, however, makes queues even longer as the benefits to queuing increase for individuals with relatively low value of time. This effect can result in lower efficiency of the second economy allocation relative to pure rationing by queues.[26]

The consequences of the second economy growth to the Soviet society were not, of course, limited to the issues of economic efficiency in the narrow sense of the word. The impact was much broader, affecting virtually all aspects of Soviet life. As a frequent Soviet commentator on the second economy, Tatiana Koriagina observed: "The shadow economy

---

[25]With the exception of the threat of punishment all other types of transactions costs in the second economy may actually be smaller. For example, in an overregulated economy underground operations may be cheaper as the operators do not have to abide by regulations. Also, contract enforcement based on informal mechanisms (Kronman, 1985) may sometimes be superior to the third party arbitrage (Millar, 1984).

[26]This phenomenon is analyzed in Stahl and Alexeev (1985). Gang and Tower (1988) provide a simple example. The existence of privileged access to goods in short supply may make matters even worse (Alexeev, 1989). It has to be noted that these models disregard the effect on production of introduction of black markets in exchange. When resale of goods acquired in the first economy is allowed, relatively poor consumers do most of the queuing. If income is correlated with productivity this allows more productive workers to work more in production and spend less time in queues. As a result, total supply of goods goes up and queues become shorter. This is true, of course, only on the assumption that freed up workers produce something useful for consumers, which was not necessarily true in the USSR.

26

alleviates shortages in consumer markets and, at the same time, provokes their growth. The second emerges as the obverse side of the lack of imbalances in all forms. The presence of shortages produces the growth of organized criminal economic groups and the latter lead to socio-economic and political destabilization of the society."[27]

As we can see, the implications of the second economy for the efficiency of the entire economy are not unequivocal. The Soviet-type economy probably could not survive for any significant period of time without some second economy activities greasing its wheels. As long as the second economy operates on the margins, its effect seems to be mostly beneficial to the rest of the economy. When the second economy grows too large, however, its role seems to become more and more dysfunctional. Its transactions costs, such as difficulties with contract enforcement and informational problems, grow exponentially with its size, the destruction of feedback to the planners becomes more widespread causing costlier errors,[28] the managerial and workers' incentives unrelated to plan fulfillment become stronger. The growth of the second economy probably was mainly a consequence, not the principal reason for disintegration of the Soviet economic system. Nonetheless, it did apparently contribute to the deterioration of the Soviet economic performance in the 1970s and 1980s.

---

[27]Koriagina (1990), p. 113.

[28] This effect was probably exacerbated by the reluctance of the Soviet planners to take adequate account of or even to study the second economy and its influence on the first economy as shown in Section 2.

RESEARCH AGENDA

This study is, in some sense, only a pilot attempt to identify factors involved and to quantify the disruptive influence of the second economy on the income-expenditures relations in the household sector in Russia and Ukraine in the last twenty years. Several additional challenging aspects of these relations remain to be explored. At this time we are concentrating on two specific areas.

■ We have established that the degree of correspondence between state income and savings and consumer expenditures in state trade measured by R^2 got significantly weaker between 1965 and the late 1980s. We attribute this phenomenon to the growth of the second economy and its adverse impact on the recorded behavior of household in the state economy. We did not, however, address the issue of the relative order of magnitude of the second economy. How large must the second economy income be relative to the state income to adversely affect the high degree of correlation between the latter and, say, savings? For example, is the growth of the second economy income from one to five percent of state income in a given time span sufficient to produce a statistically significant drop in R^2? Or should the growth of the second economy's share be in the 40 to 60 percent range to have an impact?

Thus we have to develop an instrument for empirically measuring the sensitivity of R^2's with respect to changes in second economy variables such as income. While we do not expect to be able to deduce an accurate measure of the overall size of the second economy so rough measures of sensitivity would be useful to asses independent estimates.

■ The second aspect of the relations between money income of the population and such dependent variables as savings and expenditures we are investigating lies with the direction of the change in R^2's. If a decline of R^2's indicates a disruptive invasion of the second economy it would be reasonable to interpret an increase in values of R^2's as signifying a reduction of unrecorded illegal incomes or transactions.

As the newly independent states are moving from a centrally-planned to a market system a large share of second economy activities should be gradually legalized and the normal high degree of correspondence between incomes and expenditures should be restored. The availability of statistics necessary for such tests is uncertain at this point but reorganized statistical agencies of newly independent states, particularly in the Baltics and in Russia are experimenting with new statistical measures and publishing new income, savings, and expenditures series.   By redesigning the definition and the scope of money income and expenditures of the population and running appropriate regressions we could thus conceivably measure the progress of these countries towards markets.[29]

This should be especially interesting because up to this time scholarly studies of transition processes did not offer any comprehensive quantitative measures of progress towards markets except for presenting collections of simple ratios of private over state employment and production or shares of privatized enterprises.

---

[29]   We cannot expect all second economy activities to disappear even with the establishment of truly free consumer markets. Activities such as illegal home distillation of alcohol, smuggling, prostitution, and production and marketing of narcotics are likely to continue to be present.

APPENDIX A. DESCRIPTION OF THE DATA USED IN THE STUDY

The scope of this study was severely limited by the availability of the required Soviet data. The primary set of variables around which the entire study is built is money income of the population broken down into a number of regions of the former USSR large enough for meaningful regression analyses. These money income data were long considered secret by Soviet statistical agencies and had not been published in the open literature until the late 1980s. In fact, they remain scarce even now. The first set of per capita money income of the population for a series of years for 72 oblasts, krais, and autonomous republics of the RSFSR, and the cities of Moscow and Leningrad was included in a 1990 Goskomstat RSFSR mimeographed statistical handbook of which only 50 copies had been printed (Goskomstat RSFSR, POKAZATELI... 1990, pp. 83-84). It was precisely this set of statistics that provoked our interest and originated this study. Soon thereafter Treml was given an unpublished set of similar data for 26 oblasts and the city of Kiev by Goskomstat of the Ukraine. Despite an extensive search through all old and newly available and declassified statistical sources and direct inquiries with central statistical agencies of newly independent states no additional data on money income of the population have been obtained.[30]

The study is thus built on data on incomes and expenditures for regions of Russia and Ukraine but for different years and products.

A total of about 220 simple linear regressions (with dependent variables such as per capita bank savings and consumption of goods and services, and money income as an independent variable) were run. It should be added that we tested more variables than described below and summarized in our results. In our choice of individual consumer goods we concentrated on food products because the data were more readily available and because food is more homogenous with smaller qualitative intertemporal changes.[31] In several instances we ran regression tests on products with low income elasticity of demand, such as salt, matches, vegetable oil, and vegetables. As expected, these tests produced very low or statistically insignificant R^2's for all years and were, therefore, omitted from the study.

Under food products we tested consumption of food both in value terms and in physical units.

---

[30]Goskomstat of Belarus has published the data on money income of the population for six oblasts and the city of Minsk for two years only (1985 and 1990), and Goskomstat of Kazakhstan released income statistics for 19 oblasts and the city of Alma Ata for 1990. The absence of data for more years and of other relevant statistics such as savings and sales made these sets unusable.

[31] For example, a pilot study of sales of television sets over income produced widely fluctuating regression coefficients. The probable reason is that the mix of cheaper black-and-white and much more expensive color sets changed drastically during the period under consideration.

DEFINITIONS AND SOURCES OF DATA

1. <u>Money income of the population</u> covers all legal direct monetary payments, loans and transfers from the state to the population. The state is defined broadly to include cooperatives introduced in 1987. Money income of the population thus includes payments and transfers of funds for some private economic activities, such as sales of produce grown on subsidiary private plots to the state, or payments for collected scrap metal; it also includes payments for used goods sold by private individuals to commissary stores of the retail trade network. It excludes such transactions as sales of produce grown on subsidiary private plots to the public on urban kolkhoz markets and other legal or illegal transactions among private individuals (Gosplan et al., 1982).[32] It should be noted that unlike other data sets money income of the population published in 1990 excluded the city of Moscow. Accordingly, we had to omit the city of Moscow from all regressions.

One question which has bothered Western specialists for a long time was whether military pay and money allowances (e.g., uniform allowance, payments for public transportation during home leaves, etc) are included or excluded from various aggregate income measures published in Soviet statistics, such as average or total wages. In July 1991, Mr. Barry L. Kostinsky, Assistant Division Chief, Center of International Research, Bureau of Census and Professor Treml had several interviews with a group of statistical officials at Goskomstat USSR. We were explicitly told that data on money income of the population category were collected from state bank offices and, therefore, included military pay and allowances.

2. <u>The Time Period</u>: The study covers 1965, 1970, 1980, 1985, and 1989 (and in some cases 1990 and 1991) for Russia and 1970, 1975, 1980, 1985, and 1990 for Ukraine. It should be noted that statistical data for the variables used in the study (income, savings, and purchases of goods and services) are also available for more recent years, e.g., for Russia for 1990 and 1991. The period between 1965 and the mid to late 1980s was marked by relative stability of state consumer prices for goods and services which made it possible for us to run regressions without being concerned whether changes in quantities purchased were caused by prices changes or by other factors. Inflationary pressures which accompanied Gorbachev's *perestroika* began to be felt in state consumer markets in the late 1980s. Ideally, we should have selected 1987 or 1988 as the last year of relative price stability but data for these years were not available. Accordingly, we had no choice but to select 1989 as the last year for Russia (except for the market in alcoholic beverages the analysis of which is carried through 1991). The analysis of the last year for Ukraine was complicated by the fact that we had the

---

[32] Strictly speaking part of the so-called legal or official money income of the population is not legal. We know of the widespread practice of *pripiski*, i.e., falsified overstatement of output and wage accounts in state enterprises, particularly in construction. In these cases, funds are paid by enterprises to workers from bank disbursements and would, therefore, be counted with the official wage accounts although in fact these funds should be viewed as elements of second economy or illegal private incomes. This issue, however, does not affect the basic data definitions and the findings of this study. Falsified or not the funds paid out become a part of the money income of the population balances used by state bureaucrats in planning of retail trade.

data for the money income of the population for 1990 but the last year for which we had the needed expenditure variables was 1989. As an exception we tested the relationship of all 1989 expenditure variables against 1990 income figures.

3. <u>Savings:</u> Per capita savings deposited in savings banks at the end of the year. It should be thus noted that this category does not cover all forms of household savings. Deposits in Gosbank (a minor category), purchases of state bonds and changes in currency holdings are excluded. Since the issue of the relative stability of state consumer prices is not relevant in this case, savings over income regressions were also run for RSFSR for 1990 and 1991. Savings data broken down by regions for Ukraine was found for one year only - 1989 - and we could not, therefore, study changes in relationships between income and savings over time. As seen from the tabulated data, the low value of R^2 of 0.198 is similar to R^2 for savings-income relationships in Russia and is included in the study for illustrative purposes. (Goskomstat RSFSR, POKAZATELI... 1990, pp. 93-94; Goskomstat UkSSR, NARODNOYE..., 1990, p.98).

4. <u>Aggregate Retail Trade Values</u>. Both for Russia and Ukraine we ran regression tests on per capita overall sales in state and cooperative retail trade and three components of retail trade, i.e., sales of food products, sales of nonfood products, and public dining. All retail trade data are from Goskomstat RSFSR, POKAZATELI ... 1990; Goskomstat RSFSR, TORGOVLYA... 1991; Goskomstat Rossii, POKAZATELI... 1992; TsSU UkSSR,RADYANSKA... 1971; Goskomstat UkSSR, ROZDRIBNA... 1990, and Goskomstat UkSSR, NARODNOYE..., 1990.

5. <u>Meat, milk and dairy products, fish, and eggs.</u> We had a choice of two measures of consumption of these products. Standard Soviet statistical sources have traditionally published data on total meat, milk and dairy products, and sugar consumption, i.e., consumption combining quantities purchased in retail trade stores, with sales on urban kolkhoz markets, intra-village markets, and those produced on private auxiliary agricultural plots and consumed by producing households. Total consumption also included the use of sugar and milk and dairy products in other food processing such as baking, confections etc. The second measure available to us was meat, milk[33] and dairy products, fish and eggs delivered to the retail trade networks (*postavka v torgovlyu po rynochnomu fondu*). The latter excludes industrial uses of these products, kolkhoz market and private plot consumption and is thus more homogeneous. There is one disadvantage, however, in that deliveries are not necessarily equal to sales because of possible changes in stocks and spoilage. Testing suggested that stocks of these products in state consumer trade networks did not vary much over time and thus we accepted the deliveries as the more accurate measure of consumption.

---

[33]   Milk and milk products were reported in Soviet sources converted to standard units with 3.2 percent fat content in the 1965-1980 period. In 1985 the definition was changed to 3.6 percent fat. Maybe this change in the conversion method explains the somewhat erratic behavior of regression coefficients in 1985 and 1989.

6. <u>Alcohol.</u> Second economy is particularly widespread in alcoholic beverage markets (see Treml, "Alcohol..." 1985) and therefore as much data as could be found were included in the study. The following consumption statistics were used for Russia: purchases of all types of alcoholic beverages in retail trade in rubles, total consumption of pure alcohol (i.e., consumption of all alcoholic beverages converted to 100% alcohol dependent on the alcohol content of specific beverages), vodka, wine, and beer in liters . The data on sales of alcohol in rubles were obtained from retail trade statistics and shares of alcohol in total. For Ukraine we use sales of all alcoholic beverages in rubles and consumption of pure alcohol.

7. <u>Other food products</u>. Other food products consist of two groups. For Russia we used the data on per capita consumption of bread and sugar measured in kg. For Ukraine we found the data (unfortunately for two years only, 1970 and 1989) for state retail sales of meat, sausages, milk, butter, sugar, fish, and eggs measured in rubles.

8. <u>Consumer services</u> Soviet statistical sources classify all services paid for by the population into consumer or *bytovye* services such as repairs of soft goods and durables, laundries and dry cleaning establishments, barbershops, public baths, photography etc., and "other services" such as transportation, mail, telephones, housing and utilities, cultural, educational, entertainment, and the like. The data used in this study covers only consumer services. The somewhat erratic behavior of regression coefficients for services in Ukraine could be possibly explained by the fact that services in 1970 an 1975 were measured in constant prices of unknown and different base years. Starting in 1980 the data are in current prices.

9. <u>The Data.</u> Statistical data on money income of the population, savings, and expenditures on goods and services are shown in tables below. Tables A1-A18 cover Russia, tables A19-A27 cover Ukraine. All data are given per capita. Values are in current rubles.

Table A1. Russia. Money Income of the Population, Rubles

		1965	1970	1980	1985	1989	1990	1991

APPENDIX C. EXTENDING OUR ANALYSIS TO AN EARLIER PERIOD

As was mentioned earlier the choice of the benchmark year in our study, i.e., 1965 for Russia and 1970 for Ukraine, was dictated by data availability but it would have been interesting to extend the study to an earlier year.

Regression analyses of Russia for 1965 and Ukraine for 1970 show a high degree of correlation between per capita money income of the population and per capita aggregate consumer retail trade sales. This suggests that trade data could be substituted for the income statistics for years for which the latter were not available.

We tested this observation by testing relationships between per capita retail sales as the independent variable and per capita sales of six food products in 85 oblast and key cities in Russia in 1957 (TsSU, SOVETSKAYA..., 1958, pp. 238-339), the earliest year for which detailed regional data are available. In the absence of regional population data for 1957 we used the 1959 population census statistics (TsSU, NASELENIYE..., 1975, pp. 14-35).

As can be seen from the summary below, the results of the test were both interesting and reasonable: we found a high degree of correspondence (R^2 between 0.8 and 0.9) for such basic product groups as meat, milk, sugar, and alcoholic beverages, a lower R^2 for low-income elasticity bread, and still lower R^2 for salt. The results are also close to what we found running regressions on these products over money income in Russia and Ukraine in 1965 and 1970.

There is, however, one important exception: sales of sugar regressed over trade in 1957 yields a high R^2 of 0.842 while sugar regressed over money income for Russia in 1965 shows a R^2 of 0.269 and for Ukraine in 1970 the R^2 is 0.200. But this exception should have been expected and, in an indirect way, validates our analysis and conclusions. Sugar, a relatively expensive commodity in the Soviet Union because of the high turnover tax, should under normal circumstances display a high degree of correspondence with income (or, its proxy, total trade sales) as indeed it did in our test in 1957. The establishment of close friendly relations with the socialist Cuba in the late 1950s led, among other things, to an expansion of imports of Cuban raw sugar and a rapid growth of its supply in the USSR. As supply grew the home distillers of "samogon" (moonshine) began switching from other inputs such as potatoes, flour, and grains to sugar -- it was estimated that in the 1970s and 1980s between 15 and 20 percent of sugar sold in retail trade in the USSR was diverted from direct human consumption into the illegal home production of alcohol. This development changed the parameters of demand for sugar in the USSR and probably explains the drop in the R^2 observed between 1957 and 1965.

We can conclude from this evidence that in all probability stable and predictable relations between money income of the population and consumption of different goods and services existed as far back as the late 1950s.

---

[34] Another confirmation of the useability of the trade data for income is seen in the following test. We repeated regressions on 1965 per capita sales of three food products in Russia with total retail trade substituted for income. The R^2's so calculated were: alcohol in rubles - 0.791, meat - 0.943, milk - 0.806, and bread - 0.255, that is corresponding closely to R^2's obtained with food over income regressions (Table 1).
