Abstract

This supplement contains the Lemmas (and their proofs) that are used in the proofs of Theorems 3.1 and 3.2 of the paper in Sections S1 and S2; the proof of Corollary 3.1 in Section S2; a missing data example and Monte Carlo simulations in Section S3; the verification of Assumptions A.6 and A.7 in two leading examples in Section S4; a discussion of the intuition behind Theorem 3.2 in Section S5; and details of the computations carried out in Table 1 in Section S6.

S1 Auxiliary Lemmas

Lemma S1.1. Assume the parameter space is given by $F_n$ in Eq. (2.5) and $S$ satisfies Assumption A.1. Under any sequence $\{\gamma_n,h_n\}_{n \geq 1}$ defined in Definition A.1 for a subsequence $\{\omega_n\}_{n \geq 1}$ and $h = (h_1,h_2)$, it follows that

\[ T_{\omega_n}(\theta_{\omega_n,h}) \to_d J_h \sim S(h_2^{1/2}Z + h_1,h_2), \]  

where $T_n(\cdot)$ is the test statistic associated with $S$ and $Z = (Z_1,\ldots,Z_k) \sim N(0_k,I_k)$.

Lemma S1.2. For any $a \in (0,1)$ and $\rho \in [-1+a,1-a]$ define

\[ f(z_1,z_2,\rho) \equiv (1-\rho^2)^{-1} \min_{(t_1,t_2) \in R^2_{+,\infty}} \{ (z_1 - t_1)^2 + (z_2 - t_2)^2 - 2\rho(z_1 - t_1)(z_2 - t_2) \}. \]  

Then $f(z_1,z_2,\rho)$ takes values according to the following four cases:

1. Let $z_1 \geq 0$ and $z_2 \geq 0$. Then, $f(z_1,z_2,\rho) = 0$.

2. Let $z_1 \geq 0$ and $z_2 < 0$. If $\rho \leq z_1/z_2$, then

\[ f(z_1,z_2,\rho) = (1-\rho^2)^{-1}[(z_1 - z_2)^2 + 2(1-\rho)z_1z_2] \]  

(S1.3)
If $\rho > z_1/z_2$, then $f(z_1, z_2, \rho) = z_2^2$.

3. Let $z_1 < 0$ and $z_2 \geq 0$. If $\rho \leq z_2/z_1$, then Eq. (S1.3) holds. Otherwise $f(z_1, z_2, \rho) = z_1^2$.

4. Let $z_1 < 0$ and $z_2 < 0$. If $\rho \leq \min\{z_1/z_2, z_2/z_1\}$, then Eq. (S1.3) holds. Otherwise $f(z_1, z_2, \rho) = \max\{z_1^2, z_2^2\}$.

**Lemma S1.3.** Suppose that $k = p = 2$ and fix $\beta > 0$. For $\varepsilon > 0$ let $\rho_\varepsilon = -\sqrt{1 - \varepsilon}$, $h_{2,\varepsilon} = \left[ \frac{1}{\rho_\varepsilon} \rho_\varepsilon \right]$, and

$$H_\beta \equiv \{ h_1 \in \mathbb{R}^2 : h_{1,1} \leq -\beta, h_{1,2} \leq 0 \}.$$  \hspace{1cm} (S1.4)

Define the set $A_{\varepsilon,\beta} = A^a_{\varepsilon,\beta} \cup A^b_{\varepsilon,\beta} \cup A^c_{\varepsilon,\beta} \subseteq \mathbb{R}^2$, where

$$A^a_{\varepsilon,\beta} = \{ z \in \mathbb{R}^2 : z_1 \geq 0, z_2 < 0, 0 < z_1 - \rho_\varepsilon z_2 \leq \beta/2 \},$$  \hspace{1cm} (S1.5)

$$A^b_{\varepsilon,\beta} = \{ z \in \mathbb{R}^2 : z_1 < 0, z_2 \geq 0, 0 < z_2 - \rho_\varepsilon z_1 \leq \beta/2 \},$$  \hspace{1cm} (S1.6)

$$A^c_{\varepsilon,\beta} = \{ z \in \mathbb{R}^2 : z_1 \geq 0, z_2 < 0, z_1 - \rho_\varepsilon z_2 \leq 0 \},$$  \hspace{1cm} (S1.7)

$$A^c_{\varepsilon,\beta} = \{ z \in \mathbb{R}^2 : z_1 < 0, z_2 \geq 0, z_2 - \rho_\varepsilon z_1 \leq 0 \}.$$  \hspace{1cm} (S1.8)

and $A^c_{\varepsilon,\beta} = A^c_{\varepsilon,\beta} \cap A^c_{\varepsilon,\beta}$. Let $Z_{h_{2,\varepsilon}} \sim N(0, h_{2,\varepsilon})$. Then there exists a real valued function $\tau_\varepsilon(z, h_1) : A_{\varepsilon,\beta} \times H_\beta \to \mathbb{R}_+$ such that

$$S_2(z + h_1, h_{2,\varepsilon}) = S_2(z, h_{2,\varepsilon}) + \frac{1}{1 - \rho_\varepsilon^2} \tau_\varepsilon(z, h_1), \quad \forall z \in A_{\varepsilon,\beta}, \forall h_1 \in H_\beta,$$  \hspace{1cm} (S1.9)

and $\forall \eta, C > 0$, $\exists \varepsilon > 0$ such that

$$\inf_{h_1 \in H_\beta} \Pr \left( \frac{1}{1 - \rho_\varepsilon^2} \tau_\varepsilon(Z_{h_{2,\varepsilon}}, h_1) > C, Z_{h_{2,\varepsilon}} \in A_{\varepsilon,\beta} \right) \geq 1 - \eta.$$  \hspace{1cm} (S1.10)

### S2 Proof of Lemmas and Corollaries

**Proof of Lemma S1.1.** The proof follows along the lines of the proof of Theorem 1 in Andrews and Guggenberger (2009, AG from now on). By Lemma 1 in AG we have for any $s \in \mathbb{N}$

$$T_s(\theta_s) = S \left( \hat{D}_s^{-1/2}(\theta_s) s^{1/2} \hat{m}_s(\theta_s), \hat{D}_s^{-1/2}(\theta_s) \hat{\Sigma}_s(\theta_s) \hat{D}_s^{-1/2}(\theta_s) \right).$$  \hspace{1cm} (S2.1)

For $j = 1, \ldots, k$, define $A_{\omega, j} = \sigma_{F,j}^{-1}(\theta_s) s^{1/2} (\hat{m}_{s,j}(\theta_s) - E F_j \hat{m}_{s,j}(\theta_s))$. As in Lemma 2 in AG, we have

(i) $A_{\omega, j} = (A_{\omega,1}, \ldots, A_{\omega,k})' \to_d Z_{h_2} = (Z_{h_{2,1}}, \ldots, Z_{h_{2,k}})' \sim N(0, h_2)$ as $n \to \infty$,

(ii) $\hat{\theta}_{\omega, j}(\theta_{\omega, h}, \theta_{\omega, h})/\sigma_{F, j}(\theta_{\omega, h}) \to_p 1$ as $n \to \infty$ for $j = 1, \ldots, k$,

(iii) $\hat{D}_{\omega, j}(\theta_{\omega, h}) \hat{\Sigma}_{\omega, j}(\theta_{\omega, h}) \hat{D}_{\omega, j}^{-1}(\theta_{\omega, h}) \to_p h_2$ as $n \to \infty$.  \hspace{1cm} (S2.2)

under any sequence $\gamma_{\omega, h} = \{ (\theta_{\omega, h}, F_{\omega, h}) \}_{n \geq 1}$. These results follow from completing the sequence $\gamma_{\omega, h}$, i.e., from defining the sequence $\gamma_{s, h} = \{ \theta_{s, h}, F_{s, h} \}_{s \geq 1}$ in the following fashion. For $s \in \mathbb{N}$ define the sequence $\{ \theta_s, F_s \}_{s \geq 1}$ as follows. For any $s \leq \omega_1$, $\theta_s, F_s = (\theta_{\omega_1, h}, F_{\omega_1, h})$. For any $s > \omega_1$ and since $\{ \omega_n \}_{n \geq 1}$ is a subsequence of $N$, there exists a unique $m \in \mathbb{N}$ such that $\omega_m - 1 < s \leq \omega_m$. For every such $s$, set $\theta_s, F_s = (\theta_{\omega_m, h}, F_{\omega_m, h})$. Now let $\{ W_i \}_{i \leq n}$ be i.i.d. under $F_s$. By construction, $\forall s \in \mathbb{N}$, $\theta_s, F_s \in F_{\omega_m}$ for some $m \in \mathbb{N}$ and $\text{Corr}_{F_s}(m(W_i, \theta_s)) \to h_2$. Then, the results (i)-(iii) of Eq. (S2.2) hold by triangular array versions of central limit theorems and law of large numbers with $\omega_n, \theta_{\omega_n, h},$ and $F_{\omega_n, h}$ replaced by $s, \theta_s, \text{and } F_s$ respectively. But the convergence results along $\{ \theta_s, F_s \}_{s \geq 1}$ then imply convergence along the subsequence $\{ \theta_{\omega_n, h}, F_{\omega_n, h} \}_{n \geq 1}$, as by construction the latter coincides with the former on indices $s = \omega_n$. 

2
From Eq. (S2.2), the $j$th element of $\hat{D}_n^{1/2}(\omega_{n,h})\omega_n^{1/2}m_{\omega_n}(\omega_{n,h})$ equals $(A_{\omega_{n,j}} + \omega_n^{1/2}F_{\omega_n,h}m_{\omega_n,j}(\omega_{n,h})/\sigma_{\omega_n,h,j}(\theta_{\omega_n,h}))(1 + o_p(1))$. We next consider a $k$-vector-valued function of $\hat{D}_n^{1/2}(\omega_{n,h})\omega_n^{1/2}m_{\omega_n}(\omega_{n,h})$ that converges in distribution whether or not some elements of $h_1$ equal $\infty$. Write the right-hand side of Eq. (S2.1) as a continuous function of this $k$-vector and apply the continuous mapping theorem. Let $G(\cdot)$ be a strictly increasing continuous distribution function (df) on $\mathbb{R}$, such as the standard normal df, and let $G(\infty) = 1$. For $j = 1, \ldots, k$, we have

$$G_{\omega_n,j} \equiv G \left( \hat{\sigma}_{-\omega_{n,j}}^{-1}(\omega_{\omega_n,h})\omega_n^{1/2}m_{\omega_n,j}(\omega_{\omega_n,h}) \right)$$

$$= G \left( \hat{\sigma}_{-\omega_{n,j}}^{-1}(\omega_{\omega_n,h})\sigma_{\omega_n,h,j}(\theta_{\omega_n,h}) \right) \left[ A_{\omega_{n,j}} + \omega_n^{1/2}F_{\omega_n,h}m_{\omega_n,j}(\theta_{\omega_n,h})/\sigma_{\omega_n,h,j}(\theta_{\omega_n,h}) \right]. \tag{S2.3}$$

If $h_{1,j} < \infty$ then

$$G_{\omega_n,j} \rightarrow_d G(Z_{h_{2,j}} + h_{1,j}) \tag{S2.4}$$

by Eqs. (S2.3), (S2.2), the definition of $\gamma_{\omega_n,h}$, and the continuous mapping theorem. If $h_{1,j} = \infty$ (which can only happen for $j = 1, \ldots, p$), then

$$G_{\omega_n,j} = G \left( \hat{\sigma}_{-\omega_{n,j}}^{-1}(\omega_{\omega_n,h})\omega_n^{1/2}m_{\omega_n,j}(\omega_{\omega_n,h}) \right) \rightarrow_p 1 \tag{S2.5}$$

by Eq. (S2.3), $A_{\omega_{n,j}} = O_p(1)$, and $G(x) \rightarrow 1$ as $x \rightarrow \infty$. The results in Eqs. (S2.4)-(S2.5) hold jointly and combine to give

$$G_{\omega_n} \equiv (G_{\omega_n,1}, \ldots, G_{\omega_n,k}) \rightarrow_d (G(Z_{h_{2,1}} + h_{1,1}), \ldots, G(Z_{h_{2,k}} + h_{1,k})) = G(\infty) \tag{S2.6}$$

where $G(Z_{h_{2,j}} + h_{1,j}) = 1$ by definition when $h_{1,j} = \infty$. Let $G^{-1}$ denote the inverse of $G$. For $x = (x_1, \ldots, x_k)^T \in \mathbb{R}^k_{\infty} \times \mathbb{R}^v$, let $G(x^T) = (G(x_1), \ldots, G(x_k))^T \in (0, 1]^p \times (0, 1)^v$. For $y = (y_1, \ldots, y_k)^T \in (0, 1]^p \times (0, 1)^v$, let $G_{(k)}^{-1}(y) = (G^{-1}(y_1), \ldots, G^{-1}(y_k))^T \in \mathbb{R}^k_{\infty} \times \mathbb{R}^v$. Define $S^*(y, \Omega) = S(G_{(k)}^{-1}(y), \Omega)$ for $y \in (0, 1]^p \times (0, 1)^v$ and $\Omega \in \Psi$. By Assumption A.1(d) $S^*(y, \Omega)$ is continuous at all $(y, \Omega)$ for $y \in (0, 1]^p \times (0, 1)^v$ and $\Omega \in \Psi$. We now have

$$T_{\omega_n}(\theta_{\omega_n,h}) = S \left( G_{(k)}^{-1}(G_{\omega_n}), \hat{D}_n^{1/2}(\theta_{\omega_n,h})\hat{\Sigma}_{\omega_n}(\theta_{\omega_n,h})\hat{D}_n^{1/2}(\theta_{\omega_n,h}) \right)$$

$$\rightarrow_d S^*(G(\infty), h_2)$$

$$= S(G_{(k)}^{-1}(G(\infty)), h_2)$$

$$= S(Z_{h_2} + h_1, h_2) \sim J_h. \tag{S2.7}$$

where the convergence holds by Eqs. (S2.2), (S2.6), and the continuous mapping theorem, the last equality holds by the definitions of $G_{(k)}^{-1}$ and $G(\infty)$ and the last line hold by definition of $J_h$.

**Proof of Lemma S1.2.** The FOC associated with the minimizers $t_1$ and $t_2$ in Eq. (S1.2) are

$$-(z_1 - t_1) + \rho(z_2 - t_2) \geq 0, \quad u_1[-(z_1 - t_1) + \rho(z_2 - t_2)] = 0, \quad t_1 \geq 0, \tag{S2.8}$$

$$-(z_2 - t_2) + \rho(z_1 - t_1) \geq 0, \quad u_2[-(z_2 - t_2) + \rho(z_1 - t_1)] = 0, \quad t_2 \geq 0. \tag{S2.9}$$

The SOC are immediately satisfied as the function on the RHS of Eq. (S1.2) is strictly convex for $\rho \in [-1 + a, 1 - a]$.

Consider Case 1. In this case, $t_1 = z_1$ and $t_2 = z_2$ satisfies Eqs. (S2.8) and (S2.9) and $f(z_1, z_2, \rho) = 0$ regardless of the value of $\rho$.

Now consider Case 2. First we note that $t_1 \geq 0$, $t_2 > 0$ is not a feasible solution. This is because $t_2 > 0$ and Eq. (S2.9) imply $\rho^2(z_1 - t_1) = \rho(z_2 - t_2)$, and this together with Eq. (S2.8) results in $\rho^2(z_1 - t_1) \geq (z_1 - t_1)$ which imply $t_1 = z_1$. This results in $t_2 = z_2 < 0$ which is a contradiction. The solution must then be of the form $t_1 \geq 0$ and $t_2 = 0$. Then, it follows from the first conditions in Eq.
(S2.8) that \( t_1 \geq z_1 - \rho z_2 \), so that \( t_1 = \max\{z_1 - \rho z_2, 0\} \) and \( t_2 = 0 \) is the solution. This is a strictly convex optimization problem and so the solution exists and is unique. Then, if \( \rho \leq z_1 / z_2 \), the unique solution is \((t_1, t_2) = (0, 0)\) and the objective function is given by Eq. (S1.3). On the other hand, if \( \rho < z_1 / z_2 \), \((t_1, t_2) = (z_1 - \rho z_2, 0)\) is the unique solution and

\[
f(z_1, z_2, \rho) = (1 - \rho^2)^{-1} \left\{ (z_1 - z_1 + \rho z_2)^2 + z_2^2 - 2\rho(z_1 - z_1 + \rho z_2)(z_2) \right\} = z_2^2. \tag{S2.10}
\]

Case 3 is exactly analogous to Case 2 by exchanging the subindices 1 and 2.

Consider Case 4 then. First, we note again that \( t_1 > 0 \) and \( t_2 > 0 \) is not a feasible solution by the same arguments as before. Second, we note that \((t_1, t_2) = (0, 0)\) is a solution provided \( \rho \leq \min\{z_1 / z_2, z_2 / z_1\} \), as this condition implies the correct sign of the derivatives in Eqs. (S2.8) and (S2.9). The remaining case is either \( \rho > z_1 / z_2 \) or \( \rho > z_2 / z_1 \). By similar steps as those used in Case 2 it follows that the solution for these cases are \((t_1, t_2) = (z_1 - \rho z_2, 0)\), \( f(z_1, z_2, \rho) = z_2^2 \) and \((t_1, t_2) = (0, z_2 - \rho z_1)\), \( f(z_1, z_2, \rho) = z_1^2 \), respectively. This completes the proof.

\[
\square
\]

**Proof of Lemma S1.3.** Note that for \( \tilde{z}_j = z_j + h_{1,j}, j = 1, 2, \)
\[
S_2(z + h_1, h_2, \varepsilon) = (1 - \rho^2)^{-1} \min_{t \in \mathbb{R}_+} \left\{ \left( \tilde{z}_1 - t_1 \right)^2 + \left( \tilde{z}_2 - t_2 \right)^2 - 2\rho c (\tilde{z}_1 - t_1)(\tilde{z}_2 - t_2) \right\}. \tag{S2.11}
\]

The RHS of Eq. (S2.11) is the same optimization problem as the one in Lemma S1.2. For \( z \in A_{\varepsilon, \beta} \) and \( h_1 \in H_\beta \), Case 1 of Lemma S1.2 cannot occur and Cases 2-4 always end up with the subcase that leads to Eq. (S1.3). This is because \( \beta / 2 \leq \rho c_{1, 2} - h_{1, 1} \) and for \( \varepsilon < 1 / 2 \), \( \beta / 2 \leq -h_{1, 2} + \rho c_{1, 1} \). It follows from Lemma S1.2 that the solution of Eq. (S2.11) for \( z \in A_{\varepsilon, \beta} \) and \( h_1 \in H_\beta \) is
\[
S_2(z + h_1, h_2, \varepsilon) = (1 - \rho^2)^{-1} \left\{ (z_1 + h_{1,1} - z_2 - h_{1,2})^2 + 2(1 - \rho c)(z_1 + h_{1,1})(z_2 + h_{1,2}) \right\}. \tag{S2.12}
\]

In addition, it follows from Lemma S1.2 that the solution when \( h_{1,1} = h_{1,2} = 0 \) is given by \( S_2(z, h_{2, \varepsilon}) = z_2^2 \) for \( z \in A_{\varepsilon, \beta}^b \), \( S_2(z, h_{2, \varepsilon}) = z_2^2 \) for \( z \in A_{\varepsilon, \beta}^c \), and \( S_2(z, h_{2, \varepsilon}) = z_1^2 + (z_2 - \rho c z_1)^2 / (1 - \rho^2) \) for \( z \in A_{\varepsilon, \beta}^a \).

By some algebra it follows that
\[
S_2(z + h_1, h_2, \varepsilon) = S_2(z, h_{2, \varepsilon}) + \frac{1}{1 - \rho^2} \tau_{\varepsilon,l}(z, h_1) \quad \forall z \in A_{\varepsilon, \beta}^l, \forall h_1 \in H_\beta, \ l \in \{a, b, c\}, \tag{S2.13}
\]

where
\[
\tau_{\varepsilon,a}(z, h_1) = (z_1 + h_{1,1} - \rho c_{1,2} + h_{1,2})^2 + (1 - \rho^2)(h_{1,2}^2 + 2z_2 h_{1,2}), \tag{S2.14}
\]
\[
\tau_{\varepsilon,b}(z, h_1) = (z_2 + h_{1,2} - \rho c_{1,1} + h_{1,1})^2 + (1 - \rho^2)(h_{1,1}^2 + 2z_1 h_{1,1}), \tag{S2.15}
\]
\[
\tau_{\varepsilon,c}(z, h_1) = (h_{1,1} - h_{1,2})^2 + 2((z_2 - \rho c z_1)(h_{1,2} - \rho c h_{1,1}) + h_{1,1} z_1 (1 - \rho^2) + (1 - \rho c) h_{1,1} h_{1,2}). \tag{S2.16}
\]

Additional algebra shows that \( \tau_{\varepsilon,a}(z, h_1) \geq \beta^2 / 4 \) on \( A_{\varepsilon, \beta}^a \times H_\beta \), \( \tau_{\varepsilon,b}(z, h_1) \geq \beta^2 / 6 \) on \( A_{\varepsilon, \beta}^b \times H_\beta \) for \( \varepsilon < 1 / 2 \), and \( \tau_{\varepsilon,c}(z, h_1) \geq \beta^2 / 4 \) on \( A_{\varepsilon, \beta}^c \times H_\beta \). Thus, letting
\[
\tau_{\varepsilon}(z, h_1) = \sum_{l \in \{a, b, c\}} \tau_{\varepsilon,l}(z, h_1) I(z \in A_{\varepsilon, \beta}^l), \tag{S2.17}
\]

it follows that \( \tau_{\varepsilon}(z, h_1) \geq \beta^2 / 6 \) on \( A_{\varepsilon, \beta} \times H_\beta \). We can conclude that for any constant \( C \in (0, \infty) \) there exists \( \varepsilon < (0, 1) \) such that

\[
\inf_{h_1 \in H_\beta} \Pr \left( \frac{1}{1 - \rho^2} \tau_{\varepsilon}(Z_{h_{2, \varepsilon}}, h_1) > C, Z_{h_{2, \varepsilon}} \in A_{\varepsilon, \beta} \right) \geq \Pr \left( \frac{\beta^2}{6(1 - \rho^2)} > C, Z_{h_{2, \varepsilon}} \in A_{\varepsilon, \beta} \right),
\]

\[
= \Pr \left( Z_{h_{2, \varepsilon}} \in A_{\varepsilon, \beta} \right). \tag{S2.18}
\]
Finally, define the set $A_{ε,δ}^{ε_1} \equiv A_{ε,β}^b \cup A_{ε,δ}^{ε_1}$. Note that we can write $Z_{h_{2,ε},1} - \rho_ε Z_{h_{2,ε},2} = \sqrt{1 - \rho_ε^2} W$ for $Z_{h_{2,ε},2} \perp W \sim N(0, 1)$. Then,

$$\Pr(Z_{h_{2,ε}} \in A_{ε,δ}^{ε_1}) = \Pr \left( Z_{h_{2,ε},2} \leq \min \{0, \frac{\sqrt{1 - \rho_ε^2} W}{-\rho_ε} \}, W \leq \frac{\beta}{2\sqrt{1 - \rho_ε^2}} \right) \to 1/2, \text{ as } \rho_ε \to -1. \quad (S2.19)$$

The same applies for the set $A_{ε,δ}^{ε_2} \equiv A_{ε,β}^b \cup A_{ε,δ}^{ε_2}$. By continuity in $\rho_ε$, it follows that $\forall \eta > 0, \exists \epsilon > 0$ such that

$$\Pr(Z_{h_{2,ε}} \in A_{ε,δ}^{ε_2}) \geq 1 - \eta. \quad (S2.20)$$

The result then follows from Eq. (S2.18) and (S2.20).

**Proof of Corollary 3.1.** Let $ε > 0$. Define the test function $\tilde{S}_{2,ε}(m, Ω)$ as in Eq. (3.5) and the parameter space $Ψ_{2,ε}$. Let $f_ε : Ψ_1 \to V_k \times k$ be defined as

$$f_ε(Ω) \equiv Ω + \max \{ε - \det(Ω), 0\} I_k, \quad (S2.21)$$

and note that $f_ε(\cdot)$ is a continuous function. By construction, the matrix $f_ε(Ω)$ has a determinant that is bounded away from zero, i.e., $\exists C > 0$ such that $\inf_{Ω \in Ψ_1} \det(f_ε(Ω)) \geq C$. As

$$\tilde{S}_{2,ε}(m, Ω) = \inf_{t = (t_1, \ldots, t_η) \in \mathbb{R}_{+}^k} (m - t)^t f_ε(Ω)^{-1} (m - t), \quad (S2.22)$$

it follows that $\tilde{S}_{2,ε}(m, Ω)$ is continuous at all $Ω \in Ψ_1$ and so it satisfies Assumptions A.1-A.3. By Lemmas S1.1 and B.1 it follows that

$$\text{AsySz}^2_{PA} = \inf_{h \in \{h_1, h_2\} \in H} \Pr \left( \tilde{S}_{2,ε}(Z_{h_2} + h_1, h_2) \leq c_0(h_2, 1 - \alpha) \right). \quad (S2.23)$$

Next note that for all $h_2 \in Ψ_{2,ε}$, we have $f_ε(h_2) = h_2$ and so it follows that $\tilde{S}_{2,ε}(m, h_2) = S_2(m, h_2)$ for all $m \in \mathbb{R}_{+}^k \times \mathbb{R}^n$ and $h_2 \in Ψ_{2,ε}$. Since $Ψ_{2,ε} \subset Ψ_1$, we have

$$\text{AsySz}^2_{PA} \leq \text{AsySz}^2_{SS}. \quad (S2.24)$$

It follows from Theorem 3.2 that for every $η > 0, \exists \epsilon > 0$ such that $\text{AsySz}^2_{PA} < η$. By the proof of Theorem 3.1, $\text{AsySz}^2_{PA} \geq \text{AsySz}^2_{SS} \geq \text{AsySz}^2_{GMS}$ and this completes the proof. \qed

**S3 Missing Data Example with Simulations**

**Example S3.1** (Missing Data). Suppose that the economic model indicates that

$$E_{F_0} (Y | X = x) = G(x, θ_0), \forall x \in S_X, \quad (S3.1)$$

where $θ_0$ is the true parameter value and $S_X = \{x_1\}_{i=1}^d$ is the (finite) support of $X$. The sample is affected by missing data on $Y$. Denote by $Z$ the binary variable that takes value of one if $Y$ is observed and zero if $Y$ is missing. Conditional on $X = x$, $Y$ has logical lower and upper bounds given by $Y_L(x)$ and $Y_H(x)$, respectively. The observed data are $W_i = (W_i Z_i, Z_i, X_i)$. When the observed data comes from the model in Eq. (S3.1), the true $θ_0$ satisfies the following inequalities for $i = 1, \ldots, d_x$,

$$E_{F_0, m_i, 1}(W_i, θ_0) \equiv E_{F_0}(YZ + Y_H(x_i)(1 - Z) - G(x_i, θ_0)) I(X = x_i) \geq 0,$$

$$E_{F_0, m_i, 2}(W_i, θ_0) \equiv E_{F_0}[(G(x_i, θ_0) - YZ - Y_L(x_i)(1 - Z)) I(X = x_i)] \geq 0. \quad (S3.2)$$

Notice that when $\{Y | X = x_i\}$ is fully observed (i.e. $\Pr(Z | X = x_i) = 1$), Eq. (S3.2) implies the following equation

$$E_{F_0, m_i}(W_i, θ_0) \equiv E_{F_0}[(Y - G(x_i, θ_0)) I(X = x_i)] = 0. \quad (S3.3)$$

5
Now suppose that in fact the data come from a local perturbation \( F_n \) of the hypothesized model \( F_0 \) such that
\[
E_{F_n} (Y|X = x_l) = G_n (x_l, \theta_0), \quad \forall l = 1, \ldots, d_x,
\]
and for a vector \( r \in \mathbb{R}_+^{d_x} \)
\[
|G_n(x_l, \theta_0) - G(x_l, \theta_0)| \leq rn^{-1/2}, \quad \forall l = 1, \ldots, d_x.
\]
This last condition says that the true function \( G_n \) is not too distant from the model \( G \) used by the researcher. After a few manipulations, it follows that for \( l = 1, \ldots, d_x \),
\[
E_{F_n} m_{l,1}(W_l, \theta_0) = E_{F_n} [(YZ + YH(x_l)(1 - Z) - G(x_l, \theta_0))I(X = x_l)] \geq -rn^{-1/2},
\]
\[
E_{F_n} m_{l,2}(W_l, \theta_0) = E_{F_n} [(G(x_l, \theta_0)) - YZ - YL(x_l)(1 - Z))I(X = x_l)] \geq -rn^{-1/2},
\]
and when \( \{Y|X = x_l\} \) is fully observed, Eq. (S3.5) implies the following moment condition
\[
E_{F_n} m_l(W_l, \theta_0) = E_{F_n} [(Y - G(x_l, \theta_0))I(X = x_l)] \leq rn^{-1/2}.
\]
Therefore, under the perturbed distribution of the data the original moment conditions, Eqs. (S3.2) and (S3.3), may be locally violated at \( \theta_0 \).

### S3.1 Numerical Simulations

In this section we describe a small simulation study in order to assess the finite sample relevance of the asymptotic results in Theorem 3.1. We simulate data according to Example S3.1 using the following parametrization for the data generating process: \( \theta_0 = (0.1, -0.5) \), \( S_X = \{(1,0), (0,1)\} \) (i.e. \( d_x = 2 \), \( \Pr(X = (1,0)) = \Pr(X = (0,1)) = 0.5 \), \( Y \in \{0,1\} \) is a binary random variable, \( G(x, \theta) = \Phi(\theta' x) \), where \( \Phi(\cdot) \) denotes the standard normal cumulative distribution function (i.e. \( F_0 \) implies that this is a Probit model), and \( \Pr(Z = 1|X = x) = I(x = (1,0)) + 0.5 I(x = (0,1)) \). According to the parametrization, \( Y \) is always observed when \( X = (1,0) \). The model then results in two moment inequalities and one moment equality (i.e. \( p = 2 \) and \( k = 3 \)). We compare PA, subsampling, and GMS critical values together with the test function \( S_1 \) from Eq. (2.9).

The remaining parameters of the simulation are as follows. The sample size is \( n = 1,000 \) and the number of Monte Carlo simulations is \( MC = 500 \). All of the critical values are approximated by simulation and, in every case, a total of \( B = 200 \) simulations are used. The subsampling block size \( b \) is allowed to be \( 2n/25, (2n/25 + n^{1/2}/2, \) and \( n^{1/2} \), resulting in three subsampling procedures: SS1, SS2, and SS3, respectively. The GMS tuning parameter \( \kappa_n \) is allowed to be \( \ln \ln n, (\ln \ln n + \ln n)/2, \) and \( \ln n \), resulting in three GMS procedures: GMS1, GMS2, and GMS3, respectively. Finally, we take \( r_l = r^* \geq 0 \) for \( l = 1, 2, 3 \), where \( r^*n^{-1/2} \) is allowed to be any number in an equally spaced grid of numbers from 0 to 0.1.2

For simplicity, instead of focusing on the distortions in the confidence size of the CSs we look at the distortions in the size of tests for the null hypothesis \( H_0 : \theta_0 = (0.1, -0.5) \). This substitution simplifies the computations significantly and provides conclusions that can also be applied to the confidence size of CSs, as explained in Remark 2.3. Under the null hypothesis it follows that
\[
E_{F_0}(Y|X = (1,0)) = 0.54 \text{ and } E_{F_0}(Y|X = (0,1)) = 0.31.
\]
A perturbation \( F' \) of \( F_0 \) results in different values of the expectations \( E_{F'}(Y|X = x) \).3 In our simulation exercise, we consider the set of all distributions \( F' \) that would result in values of \( E_{F'}(Y|X = x) \) that are in a small neighborhood of the predictions of the model under the null hypothesis. In

---

1For simplicity, we also assume that the distributions of \( X \) and \( Z \) are known and fixed by design and, thus, the researcher is effectively conducting inference about the (conditional) distribution of \( Y \).

2For \( r^*n^{-1/2} \geq 0.1 \), all of the inferential methods are 100% distorted.

3For example, if the model was a Logit model, then \( E_{F'}(Y|x = (1,0)) = \Lambda(0.1) = 0.53 \) and \( E_{F'}(Y|x = (0,1)) = \Lambda(-0.5) = 0.38 \), where \( \Lambda \) denotes the logistic cumulative distribution function.
Simulation parameters: \( n = 1,000, MC = 500, B = 200, b = \{2n/25, (2n/25 + n^{1/2})/2, n^{1/2}\}\), \( \kappa_n = \{\ln \ln n, (\ln \ln n + \ln n)/2, \ln n\}\), and \( \alpha = 0.10\).

In particular for any \( r^* \geq 0\), we consider the set of models \( \mathcal{F}_{r^*}\) defined as follows

\[
\mathcal{F}_{r^*} = \left\{ F' \in \mathcal{P} : \left[ \begin{array}{l}
\left( E_{F'} m_1(W_i, \theta_0)/\sigma_{F',1}^2(\theta_0) \right) \leq r^* n^{-1/2} \\
\left( E_{F'} m_2(W_i, \theta_0)/\sigma_{F',2}^2(\theta_0) \right) \leq r^* n^{-1/2} \\
\left( E_{F'} m_3(W_i, \theta_0)/\sigma_{F',3}^2(\theta_0) \right) \leq r^* n^{-1/2}
\end{array} \right] \right\},
\]

where \( \mathcal{P} \) is the set of all distributions that satisfy the restrictions of the data generating process and

\[
\begin{align*}
m_1(W_i, \theta_0) &= (YZ + (1 - Z) - G(X_i, \theta_0))I(X_i = (0,1)), \\
m_2(W_i, \theta_0) &= (G(X_i, \theta_0) - YZ)I(X_i = (0,1)), \\
m_3(W_i, \theta_0) &= (Y - G(X_i, \theta_0))I(X_i = (1,0)).
\end{align*}
\]

Given a value of \( r^* \geq 0\) we explore all models that are in \( \mathcal{F}_{r^*}\) and compare the maximum rejection probabilities across inferential methods. This is, we report

\[
\sup_{F' \in \mathcal{F}_{r^*}} \Pr_F(T_n(\theta_0) > c_n(\theta_0, 1 - \alpha)),
\]

for each choice of critical value, which involves simulating data from all \( F' \in \mathcal{F}_{r^*}\).

Under correct specification (i.e. \( r^* = 0\)) and in the limit, the hypothesis tests based on PA is conservative whereas the ones based on subsampling and GMS are size correct. Table S1 reports the empirical rejection rates under correct specification for each inferential method for a size of \( \alpha = 0.10\). As expected, PA appears to be conservative and GMS appear to be size correct, whereas subsampling is unexpectedly very conservative. These differences between the rejection rates and size under correct specification will complicate the comparison across methods as we allow for misspecification. In order to make the results comparable, we size correct the maximum rejection probabilities so that they are all equal to the size. Finally, we also report the non-corrected results for PA, as it is actually conservative.

The results are reported in Table S2. The results reveal that the non-corrected PA has a smaller maximum rejection probability than subsampling or GMS for all levels of misspecification. Furthermore, the corrected PA, subsampling, and GMS have very similar maximum rejection probabilities for all levels of misspecification. In particular, the finite sample rejection probabilities of GMS and subsampling are very similar and the differences are not statistically significant given the \( MC = 500\) simulations. All these results are in line with Theorem 3.1. Finally, the table also illustrates that the robustness of PA is related to the fact that the method is conservative under correct specification.

\[\text{The optimization problem in Eq. (S3.11) was solved numerically. The details of this computation are as follows. We selected a fine grid of 15,000 points in } \Theta = [0, 1]^2: 10,201 \text{ of them were chosen equidistantly and the remaining ones were chosen at random using a distribution with a high concentration around } F_0. \text{ For all of these points, we computed the rejection probability. Finally, in order to compute Eq. (S3.11) for a particular value of } r^*, \text{ we determine which subset of the 15,000 points belongs to } \mathcal{F}_{r^*} \text{ and report the maximum value attained in this subset.} \]
Table S2: Size-corrected maximum rejection probability over models with a maximum misspecification of $r^*n^{-1/2}$. Simulation parameters: $n = 1,000$, $MC = 500$, $B = 200$, $b = \{2n/25, (2n/25 + n^{1/2})/2, n^{1/2}\}$, $\kappa_n = \{\ln \ln n, (\ln \ln n + \ln n)/2, \ln n\}$, and $\alpha = 0.10$.

S4 Verification of Assumptions in the Examples

S4.1 Example S3.1

We start by writing the example using the notation in Definition 2.1 and using the following primitive assumption. For the assumption we use the following notation. $\Pr_n$ denotes the probability with respect to the distribution $F_n$, $I_1 \equiv I(X = x_1)$, $p_{l,n} = \Pr_n(X = x_l)$, $\pi_{l,n} = \Pr_n(Z = 1|X = x_l)$, $E_{l,n} = E_{F_n}(Y|Z = 1, X = x_l)$, $H_{l,n} = E_{F_n}(Y^2|Z = 1, X = x_l)$, and $G_{l,n} = G(x_l, \theta_n)$.

Assumption S4.1. Assume that for $c_1, c_2, c_3, c_4 \in \mathbb{R}$: (i) $p_{l,n} \geq c_1 > 0$, (ii) $H_{n,l} \leq c_2 < \infty$, $H_{n,l} - E_{n,l}^2 \geq c_3 > 0$, and $\pi_{l,n} \leq c_4 > 0$ for all $n \geq 1$ and $l = 1, \ldots, d_x$.

For simplicity assume $Y_L(x_l)$ and $Y_H(x_l)$ are both finite for all $l = 1, \ldots, d_x$. Without loss of generality, assume that $Y_L(x_l) = 0$ and $Y_H(x_l) = 1$ so that

$$
\gamma_{1,l,n} \equiv \sigma_{F_{n,l,1}}^{-1}E_{F_n} m_{1,l}(W_l, \theta_n) = \sigma_{F_{n,l,1}}^{-1}E_{F_n}[(YZ - G(x_l, \theta_n) + 1 - Z)I_l],
$$

(S4.1)

$$
= \sigma_{F_{n,l,1}}^{-1}(\pi_{l,n}E_{l,n} - G_{l,n} + (1 - \pi_{l,n}))p_{l,n} \geq -r_{l,1}n^{-1/2},
$$

(S4.2)

$$
\gamma_{1,l,2} \equiv \sigma_{F_{n,l,2}}^{-1}E_{F_n} m_{2,l}(W_l, \theta_n) = \sigma_{F_{n,l,2}}^{-1}E_{F_n}[(G(x_l, \theta_n) - YZ)I_l],
$$

(S4.3)

$$
= \sigma_{F_{n,l,2}}^{-1}(G_{l,n} - E_{l,n}\pi_{l,n})p_{l,n} \geq -r_{l,2}n^{-1/2},
$$

(S4.4)

where $\sigma_{F_{n,l,j}}^2 \equiv V_{F_n}(m_{j,l}(W_l, \theta_n))$ for $j = 1, 2$ and $l = 1, \ldots, d_x$ is given by

$$
\sigma_{F_{n,l,1}}^2 = p_{l,n}\pi_{l,n}\left((H_{l,n} - E_{l,n}^2) + (1 - \pi_{l,n})(1 - E_{l,n})^2\right),
$$

(S4.5)

$$
\sigma_{F_{n,l,2}}^2 = p_{l,n}\pi_{l,n}\left((H_{l,n} - E_{l,n}^2) + (1 - \pi_{l,n})(E_{l,n} - 2G_{l,n})^2\right).
$$

(S4.6)
Also, for \( l = 1, \ldots, d_x \)

\[
\rho_{12,l,n} \equiv E_{F_n}(m_{1,l}(W_i, \theta_n)m_{2,l}(W_i, \theta_n)) = E_{F_n}[(YZ - G_{l,n} + 1 - Z)(G_{l,n} - YZ)I_l] \tag{S4.7}
\]

\[
= (1 - \pi_{l,n})p_{l,n}[G_{l,n}(1 - p_{l,n}) + E_{l,n}n\pi_{l,n}p_{l,n}] - \sigma_{F_{n,l,t,2}}^2. \tag{S4.8}
\]

This model satisfies the following relationship

\[
m_{l,1}(W_i, \theta_n) + m_{l,2}(W_i, \theta_n) = (1 - Z)I_l, \tag{S4.9}
\]

for \( l = 1, \ldots, d_x \), so that

\[
\gamma_{1,l,1,n} = \sigma_{F_{n,l,1}}^{-1}(1 - \pi_{l,n})p_{l,n} - \sigma_{F_{n,l,1}}^{-1}\sigma_{F_{n,l,2}}\gamma_{1,l,2,n}. \tag{S4.10}
\]

### S4.1.1 On Assumption A.5

We begin with the case \( d_x = 1 \) and cover the case \( d_x > 1 \) afterwards. By Definition A.1, \( \gamma_{\omega_n}; G_{1,h} \) denotes a sequence of parameter vectors \( \theta_{\omega_n} \) and distributions \( F_{\omega_n} \) for \( W_i \) such that \( \omega_n^{1/2}\gamma_{1,j,\omega_n} \to h_{1,j} \) and \( b_n^{1/2}\gamma_{1,j,\omega_n} \to g_{1,j} \) for \( j \in \{1, 2\} \).

For a given \( \gamma_{\omega_n}; G_{1,h} \) denote by \( J \) the set of \( j \in \{1, 2\} \) that satisfy \( h_{1,j} = \infty \) and \( g_{1,j} < \infty \). By Assumption S4.1, there are constants \( 0 < B_1 < B_2 < \infty \) such that \( \sigma_{F_{n,j}} \in [B_1, B_2] \) for all \( j \in \{1, 2\} \) and \( n \in \mathbb{N} \), which implies that \( E_{F_n}m_j(W_i, \theta_n) = o(1) \) for all \( j \in J \). When \( J \) is empty, there is nothing to show. We are therefore left with cases (I) \( J = \{1\} \), (II) \( J = \{2\} \), and (III) \( J = \{1, 2\} \). We start with the case \( J = \{1\} \) and consider two subcases. In Case (a) \( h_{1,2} < \infty \) while in Case (b) we have \( h_{1,2} = \infty \) and \( g_{1,2} = \infty \). To simplify notation we write \( n \) rather than \( \omega_n \) and \( b_n \) instead of \( b_n \).

**Case (I)(a):** Since \( h_{1,2} < \infty \), it follows by previous arguments that \( E_{F_n}m_{2}(W_i, \theta_n) = o(1) \). By Eq. (S4.9), \( (1 - \pi_{n}) = o(1) \) and \( E_n = G_n + o(1) \). It then follows that \( \rho_{12,n} \to -1 \). Consider an alternative sequence of parameters \( \{\theta_n', F'_n\}_{n \geq 1} \) such that \( \theta_n' = \theta_n \) (so \( G'_n = G_n \)), \( H'_{n} = H_{n}, \pi'_n \) and \( E'_n \) given by

\[
\pi'_n = 1 - (\ln b)b^{-1/2} \to 1, \tag{S4.11}
\]

\[
E'_n = (G_n + h_{1,2}\sigma_{F_{n,2}}n^{-1/2} - (\ln b)b^{-1/2})\left(1 - (\ln b)b^{-1/2}\right)^{-1} = E_n + o(1). \tag{S4.12}
\]

This implies

\[
(1 - \pi'_n) = (\ln b)b^{-1/2} = o(1), \tag{S4.13}
\]

\[
(G'_n - \pi'_nE'_n) = -h_{1,2}\sigma_{F_{n,2}}n^{-1/2} + (\ln b)b^{-1/2} = o(1), \tag{S4.14}
\]

and \( \sigma_{F_{n,j}}^{-1} = 1 + o(1) \) for \( j = 1, 2 \). As a result

\[
b^{1/2}\sigma_{F_{n,1}}^{-1}E'_{F_n}m_1(W_i, \theta_n') = \sigma_{F_{n,1}}^{-1}\left(-b^{1/2}(h_{1,2}\sigma_{F_{n,1}})n^{-1/2} + \ln b\right) \to \infty, \tag{S4.15}
\]

\[
n^{1/2}\sigma_{F_{n,2}}^{-1}E'_{F_n}m_2(W_i, \theta_n') = \sigma_{F_{n,2}}^{-1}(h_{1,2}\sigma_{F_{n,1}}) \to h_{1,2}. \tag{S4.16}
\]

Finally, by \( \pi' \to 1 \) and Assumption S4.1, \( \rho'_{12,n} \equiv Corr_{F_n}(m_1(W_i, \theta_n'), m_2(W_i, \theta_n')) \to -1 \).

**Case (I)(b):** Since \( \sigma_{F_{n,2}} \in [B_1, B_2] \), it follows that \( \lim E_{F_n}m_2(W_i, \theta_n) \in [0, \infty] \). In this case \( \lim (1 - \pi_n) \in [0, 1] \). Consider an alternative sequence of parameters \( \{\theta_n', F'_n\}_{n \geq 1} \) such that \( \theta_n' = \theta_n \) (so \( G'_n = G_n \)), \( H'_{n} = H_{n}, \pi'_n \) and \( E'_n \) given by

\[
\pi'_n = \pi_n - 2(\ln b)b^{-1/2} = \pi_n + o(1), \tag{S4.17}
\]

\[
E'_n = \left(\pi_nE_n - (\ln b)b^{-1/2}\right)\left(\pi_n - 2(\ln b)b^{-1/2)\right)^{-1} = E_n + o(1). \tag{S4.18}
\]
where we used $\pi_n \geq c_4 > 0$. This implies $\sigma_{F_n,3}^{-1} \sigma_{F_n,3}^{-1} = 1 + o(1)$ for $j = 1, 2$. It then follows that
\[
b^{1/2} \sigma_{F_n,1}^{-1} \sigma_{F_n,1}^{-1} E_{F_n,m_1}(W_i, \theta_n', \theta_n) = b^{1/2} \sigma_{F_n,1}^{-1} \sigma_{F_n,1}^{-1} E_{F_n,m_1}(W_i, \theta_n) + o(1), \tag{S4.19}
\]
\[
b^{1/2} \sigma_{F_n,2}^{-1} \sigma_{F_n,2}^{-1} E_{F_n,m_2}(W_i, \theta_n', \theta_n) = b^{1/2} \sigma_{F_n,2}^{-1} \sigma_{F_n,2}^{-1} E_{F_n,m_2}(W_i, \theta_n) + o(1). \tag{S4.20}
\]
Finally, Assumption S4.1 and Eq. (S4.8) imply
\[
\rho_{12,n}^f = \text{Corrr}_{F_n}(m_1(W_i, \theta_n'), m_2(W_i, \theta_n')) = \rho_{12,n} + o(1). \tag{S4.21}
\]

**Case (II):** This case is analogous to Case (I) and is therefore omitted.

**Case (III):** By Eq. (S4.9) $(1 - \pi_n) = o(1)$ and $E_n = G_n + o(1)$. As a consequence of this and Assumption S4.1, it follows that $\rho_{12,n} \rightarrow -1$. Consider an alternative sequence of parameters \{(\theta_n', F_n')\}_{n \geq 1} such that $\theta_n' = \theta_n$ (so $G_n' = G_n$, $H_n' = H_n$, $\pi_n'$, and $E_n'$ given by Eqs. (S4.17) and (S4.18)). Then, Eqs. (S4.19)-(S4.21) follow and this concludes the proof for the case $d_x = 1$.

Now consider the case $d_x > 1$. Notice that in the case with $d_x = 1$, we considered a sequence of parameters \{(\theta_n', F_n')\}_{n \geq 1} such that $\theta_n' = \theta_n$ and
\[
\begin{align*}
\sigma_{F_n,1}^{-1} & \sigma_{F_n,1}^{-1} E_{F_n,m_1}(W_i, \theta_n') = \sigma_{F_n,1}^{-1} E_{F_n,m_1}(W_i, \theta_n) + o(1), \tag{S4.22} \\
\sigma_{F_n,2}^{-1} & \sigma_{F_n,2}^{-1} E_{F_n,m_2}(W_i, \theta_n') = \sigma_{F_n,2}^{-1} E_{F_n,m_2}(W_i, \theta_n) + o(1), \tag{S4.23} \\
\text{lim Corrr}_{F_n}(m_1(W_i, \theta_n'), m_2(W_i, \theta_n')) &= \lim \text{Corrr}_{F_n}(m_1(W_i, \theta_n), m_2(W_i, \theta_n)). \tag{S4.24}
\end{align*}
\]

When $d_x > 1$, we consider an alternative sequence of parameters \{(\theta_n', F_n')\}_{n \geq 1} such that for each $l = 1, \ldots, d_x$, we set $\theta_{n,l} = \pi_{n,l}, \theta_n' = \theta_n$ (so $G_{n,l} = G_{n,l}$), and the rest of the choices of the alternative distribution would be chosen according to the corresponding case in the previous part. According to this, it follows that for every $l = 1, \ldots, d_x$,
\[
\begin{align*}
\sigma_{F_n,1,l}^{-1} \sigma_{F_n,1,l}^{-1} E_{F_n,m_1,l}(W_i, \theta_n') &= \sigma_{F_n,1,l}^{-1} E_{F_n,m_1,l}(W_i, \theta_n) + o(1), \tag{S4.25} \\
\sigma_{F_n,2,l}^{-1} \sigma_{F_n,2,l}^{-1} E_{F_n,m_2,l}(W_i, \theta_n') &= \sigma_{F_n,2,l}^{-1} E_{F_n,m_2,l}(W_i, \theta_n) + o(1), \tag{S4.26} \\
\text{lim Corrr}_{F_n}(m_{1,l}(W_i, \theta_n'), m_{2,l}(W_i, \theta_n')) &= \lim \text{Corrr}_{F_n}(m_{1,l}(W_i, \theta_n), m_{2,l}(W_i, \theta_n)). \tag{S4.27}
\end{align*}
\]

To conclude the proof, we notice that for $l, j = 1, \ldots, d_x$ with $l \neq j$ and $a, b \in \{1, 2\}$
\[
\text{Corrr}_{F_n}(m_{a,l}(W_i, \theta_n'), m_{b,k}(W_i, \theta_n')) = -\sigma_{F_n,a,l}^{-1} E_{F_n,m_{a,l}}(W_i, \theta_n') \sigma_{F_n,b,k}^{-1} E_{F_n,m_{b,k}}(W_i, \theta_n') + o(1), \\
= -\sigma_{F_n,a,l}^{-1} E_{F_n,m_{a,l}}(W_i, \theta_n) \sigma_{F_n,b,k}^{-1} E_{F_n,m_{b,k}}(W_i, \theta_n) + o(1), \\
= \text{Corrr}_{F_n}(m_{a,l}(W_i, \theta_n), m_{b,k}(W_i, \theta_n)) + o(1). \tag{S4.28}
\]

### S4.1.2 On Assumption A.6

We verify Assumption A.6 for $r^* > 0$. For simplicity consider the case $d_x = 1$. Choose a sequence of parameters \{(\theta_n, F_n)\}_{n \geq 1} with $1 - \pi_n = o(1)$ and limiting parameter $h_{n,1}^* < 0$. By Eq. (S4.10), $h_{n,2}^* = h_{n,1}^* > 0$ and $h_{n,2}^*$ is a $2 \times 2$ matrix equal to $[1, -1; -1, 1]$.

First, consider the test function $S_1$. Let $c_0(h_{n,1}^*, 1 - \alpha)$ be the $1 - \alpha$ quantile of
\[
S_1(Z_{h_2^*}, h_2^*) = [Z_1]^2 + [-Z_1]^2 = Z_1^2, \quad Z_{h_2^*} = (Z_1, Z_2) \sim N(0, h_2^*). \tag{S4.29}
\]

Note that
\[
S_1(Z_{h_2^*} + h_1^*, h_2^*) = [Z_1 + h_1^*]^2 + [-Z_1 - h_1^*]^2 = (Z_1 + h_1^*, 1)^2, \tag{S4.30}
\]
and since $\Pr((Z_1 + h_1^*)^2 \leq x) < \Pr(Z_1^2 \leq x)$ for $h_{1,1}^* < 0$, $\Pr((Z_1 + h_1^*)^2 \leq c_0(h_{n,1}^*, 1 - \alpha)) < 1 - \alpha$. Assumption A.6 then holds.

Second, consider the test function $S_2$. We consider the version of $S_2$ in Eq. (3.5) as here the limit correlation matrix is singular (i.e. the test function should be defined on $\Psi_1$). Using the definition of
\( \hat{\Sigma}_\varepsilon \) in Eq. (3.15), it follows that

\[
\hat{\Omega}_\varepsilon^* = \begin{bmatrix} 1 + \varepsilon & -1 \\ -1 & 1 + \varepsilon \end{bmatrix} \quad \text{and} \quad \hat{\Omega}_\varepsilon^{*-1} = a(\varepsilon) \begin{bmatrix} 1 + \varepsilon & 1 \\ 1 & 1 + \varepsilon \end{bmatrix},
\]

(S4.31)

where \( a(\varepsilon) = \frac{\varepsilon^2 - 1}{\varepsilon^2} \). As a result

\[
\hat{S}_2(Z_{h_\varepsilon}, \hat{\Omega}_\varepsilon^*) = (1 + \varepsilon)a(\varepsilon) \inf_{t_1 \geq 0,\ t_2 \geq 0} \{(Z_1 - t_1)^2 + (Z_2 - t_2)^2 + 2(1 + \varepsilon)^{-1}(Z_1 - t_1)(Z_2 - t_2)\}
\]

\[
= (1 + \varepsilon)a(\varepsilon) \inf_{t_1 \geq 0,\ t_2 \geq 0} \{(Z_1 - t_1)^2 + (Z_1 + t_2)^2 - 2(1 + \varepsilon)^{-1}(Z_1 - t_1)(Z_1 + t_2)\}
\]

\[
= \frac{1}{1 + \varepsilon} Z_1^2,
\]

(S4.32)

where the first equality holds by definition, the second equality holds because \( Z_{h_\varepsilon} \) is such that \( Z_2 = -Z_1 \), and the third equality by solving the optimization. Since \( Z_2 + h_{1,2}^* = -Z_1 - h_{1,1}^* \) we also have

\[
\hat{S}_2(Z_{h_\varepsilon}^* + h_{1,2}^*, \hat{\Omega}_\varepsilon^*) = \frac{1}{1 + \varepsilon} (Z_1 + h_{1,1}^*)^2,
\]

(S4.33)

where \( h_{1,1}^* < 0 \). Let \( c_0(h_{1,1}^*, 1 - \alpha) \) be the \( 1 - \alpha \) quantile of \( \hat{S}_2(Z, \hat{\Omega}_\varepsilon^*) \) in Eq. (S4.32). Since \( Pr((1 + \varepsilon)^{-1}(Z_1 + h_{1,1}^*)^2 \leq x) < Pr(Z_1^2 \leq x) \) for \( h_{1,1}^* < 0 \), \( Pr((1 + \varepsilon)^{-1}(Z_1 + h_{1,1}^*)^2 \leq c_0(h_{2,1}^*, 1 - \alpha) \) < 1 - \alpha. Assumption A.6 then holds. The general case where \( d_\varepsilon > 1 \) follows by applying the previous argument to each pair of moment inequalities.

**S4.2 Example 2.1**

We start again by writing the example using the notation in Definition 2.1. For simplicity of the argument we assume that the distribution \( G \) is uniform, as stated below.

**Assumption S4.2.** Under the distribution \( G, \ u_i = (u_{1,i}, u_{2,i}) \) is uniformly distributed on \([0, 1]^2\).

Let \( \theta_n = (\theta_{1,n}, \theta_{2,n}) \) be the true parameter vector, \( Pr_n(\cdot) \) the probability with respect to the distribution \( F_n \) of \( W_i \), \( pr_{rs,n} = Pr_n(W_{1,i} = r, W_{2,i} = s) \) for \( r, s \in \{0, 1\} \), and \( \rho_{ij,n} = \text{Corr}_{F_n}[m_j(W_i, \theta_n), m_j(W_i, \theta_n)] \) for \( i, j \in \{1, 2, 3\} \). As defined in the text, \( G_n \) denotes the true distribution of \( u_i \) for sample size \( n \). Under Assumption S4.2 we have

\[
\begin{align*}
\gamma_{1,1,n} &= \sigma_{F_n,1}^{-1} E_{F_n}[G_1(\theta_n) - W_{1,i}(1 - W_{2,i})] = \sigma_{F_n,1}^{-1} (\theta_{2,n} - p_{10,n}), \\
\gamma_{1,2,n} &= \sigma_{F_n,2}^{-1} E_{F_n}[W_{1,i}(1 - W_{2,i}) - G_2(\theta_n)] = \sigma_{F_n,2}^{-1} (p_{10,n} - (1 - \theta_{1,n})\theta_{2,n}), \\
\gamma_{1,3,n} &= \sigma_{F_n,3}^{-1} E_{F_n}[W_{1,i}W_{2,i} - G_3(\theta_n)] = \sigma_{F_n,3}^{-1} (p_{11,n} - (1 - \theta_{1,n})(1 - \theta_{2,n})).
\end{align*}
\]

(S4.34)

By simple calculations we have

\[
\begin{align*}
\sigma_{F_n,1}^2 &= \sigma_{F_n,2}^2 = Var_{F_n}[m_1(W_i, \theta_n)] = p_{10,n}(1 - p_{10,n}) \in (0, 1/4], \\
\sigma_{F_n,3}^2 &= Var_{F_n}[m_3(W_i, \theta_n)] = p_{11,n}(1 - p_{11,n}) \in (0, 1/4], \\
\rho_{12,n} &= -1, \quad \rho_{13,n} = \frac{p_{10,n}p_{11,n}}{\sigma_{F_n,1}^2}, \quad \text{and} \quad \rho_{23,n} = -\rho_{13,n},
\end{align*}
\]

(S4.35)

where zero variances have been ruled out by Definition 2.1(iv). By Definition A.1, \( \gamma_{\omega_n, g_{1,j}} \) denotes a sequence of parameter vectors \( \gamma_{\omega_n} \) and distributions \( F_{\omega_n} \) for \( W_i \) such that \( \omega_n \to \gamma_{1,j} \) and \( F_{\omega_n} \to g_{1,j} \) for \( j \in \{1, 2, 3\} \). Recall that \( \gamma_{\omega_n, g_{1,j}} \) defines \( \theta_{\omega_n} = (\theta_{1,\omega_n}, \theta_{2,\omega_n}) \) and thus defines \( G_1(\theta_{\omega_n}), G_2(\theta_{\omega_n}), \) and \( G_3(\theta_{\omega_n}) \).
**S4.2.1 On Assumption A.5**

For a given $S4.2.1$ On Assumption A.5 in Case (II) we have $h = J$ is empty, there is nothing to show. We are therefore left with the cases $J = \{1\}$ and $J = \{2\}$. We start with the case $J = \{1\}$ and consider two subcases. In Case (I) $h_{1.2} = \infty$ while in Case (II) we have $h_{1.2} = \infty$ and $g_{1.2} = \infty$. For each subcase we consider two further subcases: in Case (a) $\rho_{13,n} \to 0$ while in Case (b) $\rho_{13,n} \to \rho_{13} \in (0, 1)$. To simplify notation we write $n$ rather than $\tilde{\omega}_n$ and $b$ instead of $b_n$.

**Remark S4.1.** Note that for any positive numbers $a_{10}, a_{01}, a_{11}$ whose sum equals 1 and $\theta = (\theta_1, \theta_2) \in (0, 1)^2$, there exists a random variable $\varepsilon_i = (u_{1,i}, u_{2,i})$ on $[0, 1]^2$ with continuous distribution such that $\Pr(u_{1,i} > \theta_1 & u_{2,i} < \theta_2) = a_{10}$, $\Pr(u_{1,i} < \theta_1 & u_{2,i} > \theta_2) = a_{01}$, and $\Pr(u_{1,i} > \theta_1 & u_{2,i} > \theta_2) = a_{11}$ (and consequently $\Pr(u_{1,i} < \theta_1 & u_{2,i} < \theta_2) = 0$).

Letting $a_{10}, a_{01}, a_{11}$ play the role of $p_{10,n}, p_{01,n}, p_{11,n}$ the Remark S4.1 implies that for a given vector $\theta_n = (\theta_{1,n}, \theta_{2,n})$ any desired outcome probabilities $p_{10,n}, p_{01,n}, p_{11,n}$ can be generated by a random variable $\varepsilon_i = (u_{1,i}, u_{2,i})$ that has a continuous distribution $G_n$.

**Case (I)(a):** We have to produce a sequence $\gamma_{n,\tilde{g}_1,h}$ for which $\tilde{g}_{1,1} = \infty$, $h_{1.2}$ is a specific finite number, and the upper right element of $h_{2}$ equals 0. Define

$$p'_{10,n} = b^{-3/7}.$$  
(S4.36)

Let $\theta'_n = (\theta'_{1,n}, \theta'_{2,n})$ for $\theta'_{1,n}$ and $\theta'_{2,n}$ defined next. Pick $\theta'_{2,n} \in (0, 1)$ such that

$$G_1(\theta'_n) = \theta'_{2,n} = p'_{10,n} + b^{-1/2}(p'_{10,n}(1 - p'_{10,n}))^{1/2}b^{3/7}$$  
(S4.37)

and pick $\theta'_{1,n} \in (0, 1)$ such that

$$G_2(\theta'_n) = (1 - \theta'_{1,n})\theta'_{2,n} = p'_{10,n} - n^{-1/2}(p'_{10,n}(1 - p'_{10,n}))^{1/2}h_{1.2}.$$  
(S4.38)

This is clearly possible because $p'_{10,n} \to 0$, $|n^{-1/2}(p'_{10,n}(1 - p'_{10,n}))^{1/2}h_{1.2}| < p'_{10,n}$, and $b^{-1/2}(p'_{10,n}(1 - p'_{10,n}))^{1/2}b^{3/7} \to 0$. We have $G_1(\theta'_n) = \theta'_{2,n} = 2b^{-3/7}(1 + o(1))$, $G_2(\theta'_n) = b^{-3/7}(1 + o(1))$. Now

$$b^{-3/7}(1 + o(1)) = G_2(\theta'_n) = (1 - \theta'_{1,n})\theta'_{2,n} = 2(1 - \theta'_{1,n})b^{-3/7}(1 + o(1))$$  
(S4.39)

which implies that $\theta'_{1,n}$ cannot converge to 1. Without loss of generality we can therefore assume that $\theta'_{1,n} \to \theta'_1$ for some $\theta'_1 \in [0, 1)$. We then have

$$G_3(\theta'_n) = (1 - \theta'_{1,n})(1 - \theta'_{2,n}) \to (1 - \theta'_1).$$  
(S4.40)

Consider the function

$$f(x) \equiv x - h_{1.3}n^{-1/2}(x(1 - x))^{1/2}$$  
(S4.41)

for $x \in [0, 1]$. The function $f$ is continuous and satisfies $f(0) = 0$ and $f(1) = 1$. Therefore, for given $G_3(\theta'_n)$, the intermediate value theorem implies there exists a value $p'_{11,n}$ such that

$$G_3(\theta'_n) = p'_{11,n} - h_{1.3}n^{-1/2}(p'_{11,n}(1 - p'_{11,n}))^{1/2}.$$  
(S4.42)

Define $p'_{11,n}$ to be any value in $(0, 1)$ that satisfies Eq. (S4.42). It cannot be the case that $p'_{11,n} \to 1$ as otherwise we would have $G_3(\theta'_n) \to 1$ contradicting Eq. (S4.40). Therefore, without loss of generality $p'_{11,n} \to p'_{11}$ for some $p'_{11} \in (0, 1)$. Note that $p'_{10,n} \to 0$ and $p'_{11} \in (0, 1)$ imply that

$$p'_{13,n} = \frac{p'_{10,n}p'_{11,n}}{\sigma'_{F,n,1}\sigma'_{F,n,3}} \to 0.$$  
(S4.43)

For these given choices of $p'_{10,n}$, $p'_{11,n}$, and $\theta'_n = (\theta'_{1,n}, \theta'_{2,n})$, Remark S4.1 implies that there exists
a continuous distribution $G'_n$ for the random variable $u_i = (u_{1,i}, u_{2,i})$ such that Pr($u_{1,i} > \theta'_{1,n}$ & $u_{2,i} < \theta'_{2,n}$) = $p'_{10,n}$, Pr($u_{1,i} < \theta'_{1,n}$ & $u_{2,i} > \theta'_{2,n}$) = $1 - p'_{10,n} - p'_{11,n}$, and Pr($u_{1,i} > \theta'_{1,n}$ & $u_{2,i} > \theta'_{2,n}$) = $p'_{11,n}$. By construction all requirements are fulfilled under the sequence $\theta'_n$ and $G'_n$.

**Case (I)(b):** We have to produce a sequence $\gamma_{\omega_n, g_1, h}$ for which $\tilde{g}_{1,1} = \infty$, $h_{1,2} < \infty$ and the upper right element of $h_2$ equals $p_{13} \in (0, 1]$. Assume first that $p_{13} \in (0, 1)$. Define

$$p'_{10,n} = cb^{-1/7} \quad (S4.44)$$

for some constant $c > 0$, and define $(\theta'_{1,n}, \theta'_{2,n}) \in (0, 1)^2$ as in Eqs. (S4.37) and (S4.38). We then have

$$\theta'_{2,n} = cb^{-1/7} + c^{1/2}b^{-2/7}(1 + o(1)) \quad (S4.45)$$

Next

$$G_3(\theta'_n) = (1 - \theta'_{1,n})(1 - \theta'_{2,n}) = (1 - c^{-1/2}b^{-1/7}(1 + o(1)))(1 - cb^{-1/7}(1 + o(1))) \quad (S4.46)$$

Arguing as in Case (I)(a) there is a value $p'_{11,n} \in (0, 1)$ such that

$$G_3(\theta'_n) = p'_{11,n} - h_{1,3}n^{-1/2(p'_{11,n} - p'_{11,n})^{1/2}}. \quad (S4.47)$$

As $G_3(\theta'_n) \to 1$ we have $p'_{11,n} \to 1$. More precisely,

$$p'_{11,n} = G_3(\theta'_n) + h_{1,3}n^{-1/2(p'_{11,n} - p'_{11,n})^{1/2}} = 1 - (c^{-1/2} + c)b^{-1/7}(1 + o(1)). \quad (S4.48)$$

Therefore,

$$p'_{13,n} \equiv \left(\frac{p'_{10,n}p'_{11,n}}{(1 - p'_{10,n})(1 - p'_{11,n})}\right)^{1/2} \to \left(\frac{cb^{-1/7}(1 - (c^{-1/2} + c)b^{-1/7})}{(1 - cb^{-1/7})(c^{-1/2} + c)b^{-1/7})}\right)^{1/2} \quad (S4.49)$$

The function $(c/(c^{-1/2} + c))^{1/2}$ is continuous for $c > 0$ and converges to 1 as $c \to \infty$ and to 0 as $c \to 0$. There is therefore $c > 0$ such that $(c/(c^{-1/2} + c))^{1/2} = p_{13}$. The proof is then concluded as in Case (I)(a). If $p_{13} = 1$, the same proof applies once the constant $c$ in Eq. (S4.44) is replaced by the sequence $c_n = \ln b$ that slowly converges to infinity.

**Case (II)(a):** We have to produce a sequence $\gamma_n, g_1, h$ for which $\tilde{g}_{1,1} = \tilde{g}_{1,2} = \infty$ and the upper right element of $h_2$ equals zero. Define

$$p'_{10,n} = b^{-3/7}. \quad (S4.50)$$

Let $\theta'_n = (\theta'_{1,n}, \theta'_{2,n}) \in (0, 1)^2$ be defined as follows. Let $\theta'_{2,n} \in (0, 1)$ be such that

$$G_1(\theta'_n) = \theta'_{2,n} = p'_{10,n} + b^{-1/2(p'_{10,n} - p'_{10,n})^{1/2}b^{2/7}} \quad (S4.51)$$

and pick $\theta'_{1,n} \in (0, 1)$ such that

$$G_2(\theta'_n) = (1 - \theta'_{1,n})\theta'_{2,n} = p'_{10,n} - b^{-1/2(p'_{10,n} - p'_{10,n})^{1/2}b^{1/7}}. \quad (S4.52)$$

As in Case (I)(a) we have $G_1(\theta'_n) = 2b^{-3/7}(1 + o(1))$ and $G_2(\theta'_n) = b^{-3/7}(1 + o(1))$. Using the same steps as in Case (I)(a) we have $\theta'_{1,n} \to \theta'_1$ for some $\theta'_1 \in [0, 1)$ and thus that $G_3(\theta'_n)$ converges to a number
smaller than 1. Then again, there exists \( p'_{11,n} \) such that \( G_3(\theta'_n) = p'_{11,n} - h_{1,3} n^{-1/2}(p'_{11,n}(1-p'_{11,n}))^{1/2} \) and \( p_{11,n} \rightarrow p'_1 \) for some \( p'_1 \in [0,1) \). Therefore, we have again that \( p'_{13,n} \rightarrow 0 \) and the proof concludes as in Case (I)(i).

**Case (II)(b):** We have to produce a sequence \( \gamma_{n_1, n_2} \) for which \( \gamma_{1,1} = \gamma_{1,2} = \infty \) and the upper right element of \( h_2 \) equals \( \rho_{13} \in (0,1] \). The proof follows along the same lines as Case (I)(b) with the one difference that \( G_2(\theta'_n) \) is defined as in Eq. (S4.52).

That concludes the verification of the assumption for the case \( J = \{1\} \). Regarding the other cases, note that the case \( J = \{1,2\} \) is covered by Cases (II)(a) and (II)(b) above. The verification of the assumption in case \( J = \{2\} \) is also partially covered by Cases (II)(a) and (II)(b) and the remaining cases for \( J = \{2\} \) are similar to Cases (I)(a) and (I)(b) above for \( J = \{1\} \) and therefore omitted.

### S4.2.2 On Assumption A.6

The verification of Assumption A.6 follows almost identical steps to those used in Section S4.1.2 and is therefore omitted.

### S5 Additional Discussion on Theorem 3.2

To understand the intuition behind Theorem 3.2 it is enough to consider the case with two moment inequalities, \( p = k = 2 \), together with the limit of the PA critical value. In this case it follows from Lemma S1.1 that

\[
\text{Asy}S_{Z_{PA}}^{(1)} \leq \Pr([Z_1^* - r_1]_+^2 + [-Z_1^*]_+^2 \leq c_0(\Omega, 1 - \alpha)),
\]

(S5.1)

where \( Z^* \sim N(0, \Omega) \) and \( \Omega \in \Psi_1 \) is a correlation matrix with off-diagonal elements \( \rho = -1 \). Theorem 3.2 shows that \( \text{Asy}S_{Z_{PA}}^{(1)} \) is strictly positive provided the amount of misspecification is not too big, i.e., \( r^* \leq B \). The reason why some condition on \( r^* \) must be placed is evident: if the amount of misspecification is really big there is no way to bound the asymptotic distortion. To illustrate this, suppose \( r_1 > (2c_0(\Omega, 1 - \alpha))^{1/2} \) and let \( A \equiv [Z_1^* - r_1]^2 \) and \( B \equiv [-Z_1^*]^2 \) so that the RHS of Eq. (S5.1) is \( \Pr(A + B \leq c_0(\Omega, 1 - \alpha)) \). On the one hand, if \( Z_1^* \notin [0,r_1] \) it follows that either \( B = 0 \) and \( A > c_0(\Omega, 1 - \alpha) \) or \( A = 0 \) and \( B > c_0(\Omega, 1 - \alpha) \). On the other hand, if \( Z_1^* \in [0,r_1] \), \( A + B = (Z_1^* - r_1)^2 + Z_1^2 \geq r_1^2/2 > c_0(\Omega, 1 - \alpha) \). We can then conclude that

\[
\Pr([Z_1^* - r_1]_+^2 + [-Z_1^*]_+^2 \leq c_0(\Omega, 1 - \alpha)) = 0,
\]

(S5.2)

meaning that \( \text{Asy}S_{Z_{PA}}^{(1)} = 0 \) when \( r^* > (2c_0(\Omega, 1 - \alpha))^{1/2} \). For this level of \( r^* \), \( \text{Asy}S_{Z_{PA}}^{(2)} = 0 \) as well so both test statistics suffer from the maximum amount of distortion. Therefore, in order to get non-trivial results we must restrict the magnitude of \( r^* \) as in Theorem 3.2.

In addition, Theorem 3.2 shows that \( \text{Asy}S_{Z_{PA}}^{(2)} \) can be arbitrarily close to zero when \( \varepsilon \) in the space \( \Psi_{2,\varepsilon} \) is small. What drives this result is the possibility that at least two inequalities are violated (or one is violated and the other one is binding) and strongly negatively correlated. To illustrate this, consider again the case where \( p = k = 2 \) together with the limit of the PA critical value. By \( \Omega \in \Psi_{2,\varepsilon} \), the off-diagonal element \( \rho \) of the correlation matrix \( \Omega \) has to lie in \([-(1-\varepsilon)^{1/2}, (1-\varepsilon)^{1/2}] \). It follows from Lemma S1.1 that

\[
\text{Asy}S_{Z_{PA}}^{(2)} \leq \Pr(S_2(Z^*, r_1, \Omega_\varepsilon) \leq c_0(\Omega_\varepsilon, 1-\alpha)),
\]

(S5.3)

where \( Z^* \sim N(0, \Omega_\varepsilon) \), \( \Omega_\varepsilon \) is a matrix with \( \rho = -(1-\varepsilon)^{1/2} \), and

\[
S_2(Z^*, r_1, \Omega_\varepsilon) = \frac{1}{\varepsilon} \inf_{t \in \mathbb{R}_{+}^{2,\infty}} \left\{ \sum_{j=1}^{2}(Z_j^* - r_1 - t_j)^2 + 2(1-\varepsilon)^{1/2}(Z_1^* - r_1 - t_1)(Z_2^* - r_1 - t_2) \right\}.
\]

(S5.4)

The solution to the above optimization problem can be divided in four cases (see Lemma S1.2 for details), depending on the value of the realizations \((Z_1^*, Z_2^*)\). However, there exists a set \( A \subset \mathbb{R}^2 \) such
that for all \((z_1, z_2) \in A\)

\[
S_2(z, r_1, \Omega_\varepsilon) \geq S_2(z, 0, \Omega_\varepsilon) + \frac{2}{\varepsilon} |r_1^2 - z_1 - z_2|,
\]

(S5.5)

with \([r_1^2 - z_1 - z_2] > 0\), and \(\Pr(Z^* \in A) \to 1\) as \(\varepsilon \to 0\). It is immediate from Eq. (S5.5) that small distortions \(r_1 > 0\) can produce a value of \(S_2(Z^*, r_1, \Omega_\varepsilon)\) that is arbitrarily high on the set \(A\) by allowing \(\varepsilon\) to be arbitrarily close to zero, i.e., correlation close to -1. Since \(c_0(\Omega_\varepsilon, 1 - \alpha)\) can be shown to be bounded in \(\Psi_{2,\varepsilon}\), it follows that

\[
\Pr(S_2(Z^*, r_1, \Omega_\varepsilon) \leq c_0(\Omega_\varepsilon, 1 - \alpha)|A) \to 0,
\]

(S5.6)
as \(\varepsilon \to 0\). Therefore, Eq. (S5.3) implies that CSs based on \(S_2\) have asymptotic confidence size arbitrarily close to zero when \(\varepsilon\) is small.

### S6 Details of the Numerical Computations in Table 1

Table 1 reports a numerical approximation to the AsySz of the CSs based on \(S_1\) and \(S_2\) (with a PA critical value) using the formula in Lemma B.1, i.e.,

\[
\text{AsySz}_{PA} = \inf_{h=(h_1,h_2) \in H} \Pr(S(Z_h + h_1, h_2) \leq c_0(h_2, 1 - \alpha)),
\]

(S6.1)

where \(Z_h \sim N(0_p, h_2)\). Table 1 reports the cases where \(p \in \{2, 4, 8, 10\}\), \(k = p\), \(\varepsilon \in \{0.10, 0.05\}\), and \(r^* \in \{0.25, 0.50, 1.00\}\). Therefore, the parameter space \(H\) is given by all the \(p\) vectors \(h_1\) such that \(h_{1,j} \geq -r^*\) (i.e. \(r_j = r^*\)) for all \(j = 1, \ldots, p\), and \(h_2 \in \Psi_1\) (or \(\Psi_{2,\varepsilon}\)) for \(S_1\) (or \(S_2\)).

Having defined the parameter space \(H\), we now describe how we compute the minimizer in Eq. (S6.1). By the nature of the parameter space \(H\), the problem can be broken down into finding the worst sub-vectors \(h_1\) and \(h_2\). In the case of \(h_1\), it is not hard to show that the worst sub-vector is given by \(h_{1,j} = -r^*\) (i.e. all the inequalities are as violated as possible). The case of \(h_2\) is not as simple as it is not clear which correlation matrix is the worst case correlation when \(p > 2\). In the results presented in Table 1 we use the following three types of correlation matrix structures.

1. Matrices \(h_2\) of the form

\[
h_2 = \begin{bmatrix}
A & 0_{2 \times (p-2)} \\
0_{(p-2) \times 2} & I_{p-2}
\end{bmatrix}, \quad \text{where} \quad A = \begin{bmatrix} 1 & \rho \\ \rho & 1 \end{bmatrix},
\]

(S6.2)

and \(0_{l,s}\) denotes a \(l \times s\) matrix of zeros. This is the structure used in the proof of Theorem 3.2. For the test function \(S_2\) we set \(\rho = -\sqrt{1 - \varepsilon}\) as we know this is the worse correlation structure for this test function. For the test function \(S_1\) we consider a grid of 20 points in \([-1, 1]\) for \(\rho\) and computed Eq. (S6.1) taking the minimum on this grid. This method generates one probability for \(S_1\) and another one for \(S_2\).

2. Matrices \(h_2\) of the form

\[
h_2 = \begin{bmatrix}
A & 0 & \cdots & 0 \\
0 & A & \cdots & \vdots \\
\vdots & \ddots & \ddots & \vdots \\
0 & \cdots & 0 & A
\end{bmatrix}.
\]

(S6.3)

For the test function \(S_2\) we set \(\rho = -\sqrt{1 - \varepsilon^{2/p}}\) as we know this is the worse correlation structure for this test function. For the test function \(S_1\) we consider a grid of 20 points in \([-1, 1]\) for \(\rho\) and computed Eq. (S6.1) taking the minimum on this grid. This method again generates one probability for \(S_1\) and another one for \(S_2\).

3. Matrices \(h_2\) equal to a random matrix generated by the method of Marsaglia and Olkin (1984). We generated 15000 random correlation matrices from \(\Psi_1\) for the test function \(S_1\), and for the
test function $S_2$ we adjusted the correlation matrix in order to satisfy the restriction $\det(h_2) \geq \epsilon$ if the randomly generated matrix had a determinant below $\epsilon$. We then computed Eq. (S6.1) taking the minimum of the 15000 randomly generated matrices. Once more, the end result is one probability for $S_1$ and another one for $S_2$.

What Table 1 presents is the minimum value, for each test function $S_1$ and $S_2$, of the three probabilities derived in each of the above cases. Note that for each matrix $h_2$ in cases 1, 2, and 3 above (e.g. for each of the 15000 in case 3), we approximated the probability in Eq. (S6.1) by generating 2000 random variables with distribution $N(0, h_2)$. Step by step instructions on how to compute each of these quantities are contained in the R file included with the online Supplement Materials.
